FOREWORD

This report was prepared for the U.S. Department of the Air Force, Ballistic Missile Office (BMO), in compliance with Contract No. F04704-80-C-0006, CDRL Item 004A6. It contains an evaluation of the suitability of Muleshoe Valley, Nevada, for siting the MX Land Mobile Advanced ICBM system and presents the geological, geophysical, and soils engineering data upon which the evaluation is based. It is one of a series of reports covering the results of Verification studies in the Nevada-Utah region.

Verification studies, which were started in 1979, are the final phase of a site-selection process which was begun in 1977. The Verification objectives are to define sufficient area suitable for deployment of the MX system and to provide preliminary soils engineering data. Previous phases of the site-selection process were Screening, Characterization, and Ranking. In preparing this report, it has been assumed that the reader will be familiar with the previous studies.

Volume I of this report is a synthesis of the data obtained during the study. It contains discussions relative to the horizontal and vertical shelter basing modes. Volume II is a compilation of the data which may be used for independent interpretations or analyses.

1.0 INTRODUCTION

1.1 PURPOSE AND BACKGROUND

This report presents the results of the geotechnical studies which were completed in Muleshoe Valley, Nevada, during the fall of 1979 and summer of 1980. The work was done as part of Ertec Western, Inc's. (formerly Fugro National, Inc.) Verification studies which have two major objectives:

1. Verify and refine boundaries of areas which are geotechnically suitable for the two proposed basing modes (horizontal and vertical shelter) for the MX missile system; and
2. Provide preliminary physical and engineering characteristics of the soils.

This report contains two volumes. This volume is a synthesis of the data collected during the studies. The data obtained as a result of the field and laboratory work are compiled by activity in Volume II.

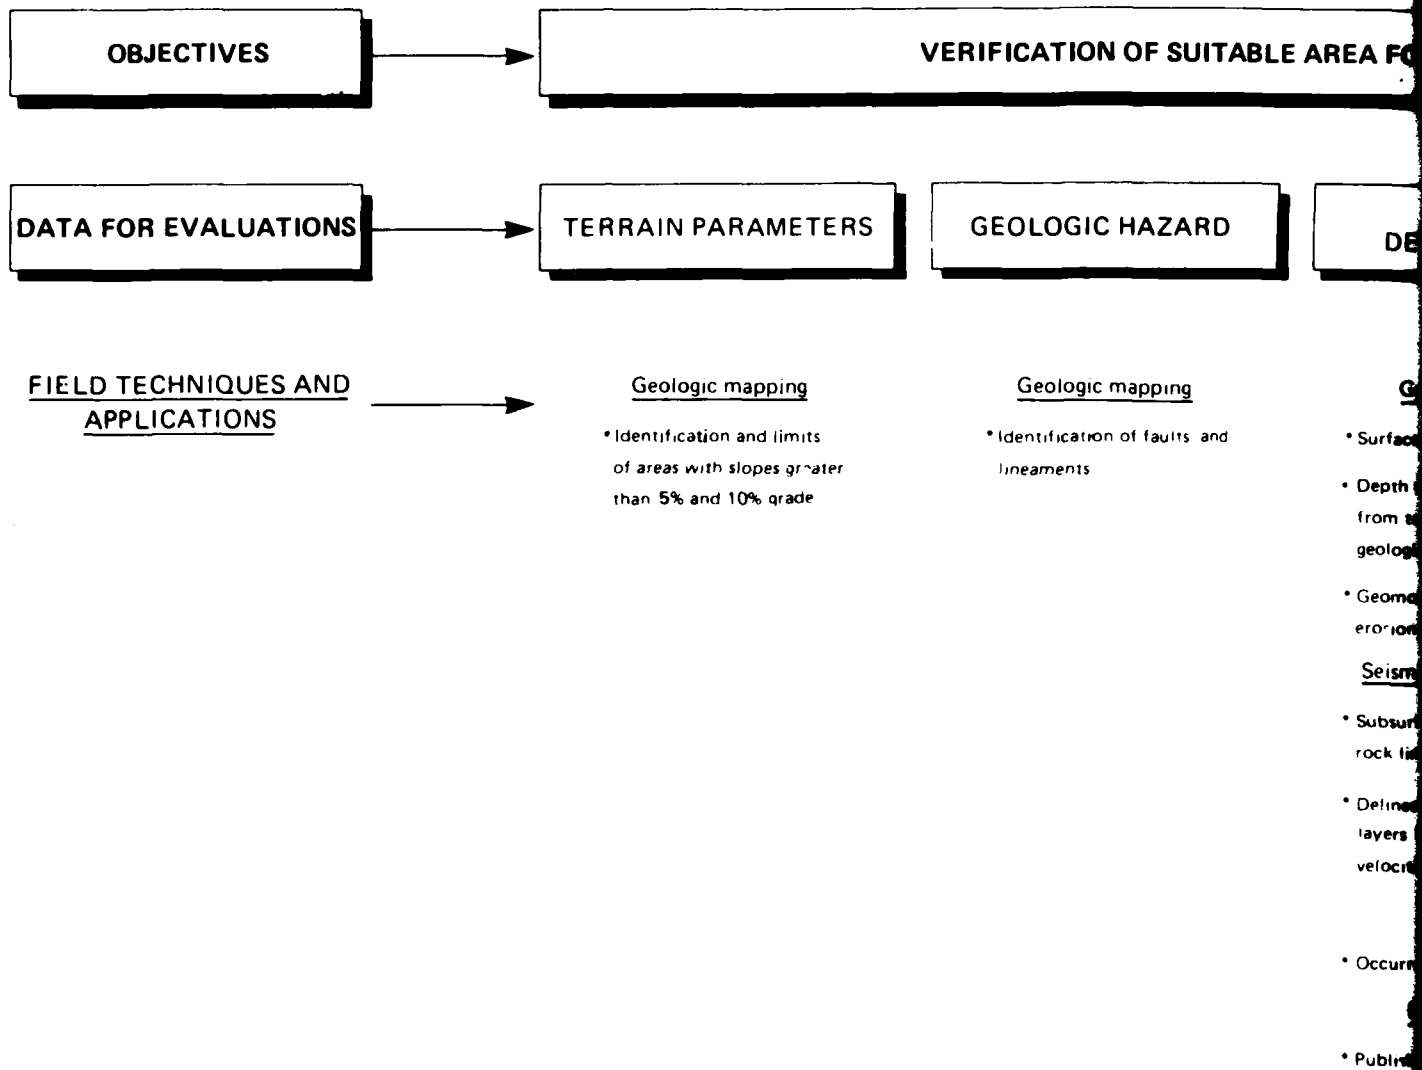

The Verification Program is the final phase of a site-selection process which started in 1977. The objective of the site-selection process is to identify and rank geotechnically suitable areas which are sufficiently large for deployment of the Missile-X (MX), an advanced intercontinental ballistic missile system. The phases involved are Screening, Characterization, Ranking, and Verification. Screening used existing information from literature to identify areas which appeared to be suitable for deployment of MX based on geotechnical, cultural, and environmental criteria. Potentially usable regions were identified in seven western states. Both Characterization and

Verification programs use field studies as well as published information. Following Screening and Characterization, the available geotechnical data were used to rank the seven regions. The ranking, based on relative construction costs, was made for various basing modes. Characterization studies emphasized collection of information to characterize geologic units with respect to construction of the MX basing options. Verification studies also obtain information on construction properties of the geologic units, but special emphasis is given to refining the usable area boundaries that were drawn during the Screening studies. Table 1-1 summarizes the investigative techniques being employed during Verification studies.

Figure 1-1 shows the site selection schedule and identifies the FNI technical report for each element in the process. Based on the results of Screening, Characterization, and Ranking, contiguous portions of Nevada and Utah were selected as a candidate siting region for the MX system, and Verification studies were started in 1978. As shown in Figure 1-1, the Verification Program is continuing, and field work should be completed in 1981. The valleys for which reports have been issued on the Verification studies are shown in Figure 1-2. The presently defined geotechnically suitable areas for the Nevada-Utah siting region are shown in Drawing 1-1. These areas will be adjusted as Verification studies are completed.

1.2 SCOPE OF STUDY

The field work in Muleshoe Valley was done in October and November, 1979 and August 1980. Table 1-2 lists the types and

SCOPE OF ACTIVITIES MULESHOE VALLEY, NEVADA

30 JUN 81

TABLE 1-2

number of field activities that were performed in Muleshoe Valley. The techniques of investigation are discussed in the appendix.

Access to public land in Muleshoe Valley was arranged through the Ely, Nevada, district office of the Bureau of Land Management (BLM). At BLM's request, all field activities were performed along existing roads or trails to minimize site disturbance. The restriction has limited the studies that could be performed in some areas. Archaeological and environmental surveys were performed at each proposed activity location. Activity locations were changed in those few places where a potential environmental or archaeological disturbance was identified.

1.3 DISCUSSION OF ANALYSIS TECHNIQUES

1.3.1 Determination of Suitable Area

The number of field activities performed during this investigation established a relatively small data base for characterizing such a large area, especially in view of its complex geology and frequent soil variations. In some cases, the environmental restrictions limited the ability to achieve an optimum distribution of data points. Nevertheless, care has been taken to optimize the information that could be obtained within specified cost and time constraints of the project. The determination of geotechnically suitable area is based on the exclusion criteria given in Appendix Table A2-1. The main attention was focused on the study of depth to rock, depth to water, terrain conditions,

and near-surface soil characteristics. Maps showing the results of these studies are included in Section 3.0 and the composite map of area suitable for deployment is included in Section 2.0.

a. Depth to rock: For a Verification study, the depth to rock is estimated, and areas where the depths to rock are less than 50 and 150 feet (15 and 46 m) are outlined by contours (Drawing 3-3). These contours are interpreted from published well data, geologic literature, boring logs, geophysical data, and field observations. The interpretation considers the presence or absence of range-bounding faults, bedding plane attitudes, topographic slopes, evidence of erosional features such as pediments, and the presence or absence of young volcanic rocks.

b. Depth to water: Only one ground-water data point is available for Muleshoe Valley and is recorded by the State of Nevada Engineer's Office (Table II-3-1, Volume II). This data point suggests that water in Muleshoe Valley is probably deeper than 150 feet (46 m). However, the overall data are an insufficient basis for conclusions and, therefore, no contours are shown in Drawing 3-4.

c. Terrain: The map of terrain conditions (Drawing 3-5) was compiled to show areas unsuitable for either vertical or horizontal shelters due to either high surface slopes or frequent deep drainage incisions (criteria are described on Appendix Table A2-1). The interpretation of terrain exclusions is based on a combination of field- and office-derived data. Field data include the visual information obtained by reconnaissance of the

areas and measurements of typical drainage incision depths. Reconnaissance frequently results in recognition of areas with locally steep slopes (for example, the sides of large and deeply incised drainages) that are not recognizable from data available in the office. Office-determined data consists of: 1) interpretation of 1:60,000-scale black and white and 1:25,000-scale color aerial photographs to determine terrain exclusions in areas lacking road access; and 2) topographic map analysis to define areas of greater than 10 percent slope.

d. Faults: The faults shown on the geologic map (Drawing 3-2) are mapped primarily from high resolution photogeologic studies and field reconnaissance. These faults are primarily Quaternary age but some late Tertiary faults may also be included. Generally, those within alluvial deposits are of Quaternary age. The faults shown within mountain blocks or at the mountain-valley contact are of unknown age but are most likely of late Tertiary and/or Quaternary age and probably have been active under the present tectonic regime. Since they are not within the siting areas, they have not been studied. Published maps also show numerous inferred faults buried under the alluvium along the mountain-valley contacts. These faults are commonly verified by geophysical studies. They may represent earthquake hazards, but since they have no surface expression, they cannot be verified by the reconnaissance methods used in the fault studies.

1.3.2 Determination of Basin-Fill Characteristics

In addition to the primary objective of refining the boundaries of the suitable area, a secondary objective was to provide preliminary physical and engineering properties of the basin-fill materials. These data will be used for preliminary engineering design studies, will assist in planning future site-specific studies, and will be used by other MX participants.

The geologic map (Drawing 3-2) showing the distribution of surficial soils is based on the interpretation of aerial photos, field mapping, and information from trenches, test pits, and surficial soil samples.

The investigations of engineering properties were designed primarily to obtain information needed for construction activities. For Verification studies, surficial soil conditions, as related to road construction, a major cost item, received particular emphasis. Emphasis was placed also on soil conditions in the upper 20 feet (6 m) to provide information to the approximate depth of excavation for the horizontal shelter basing mode.

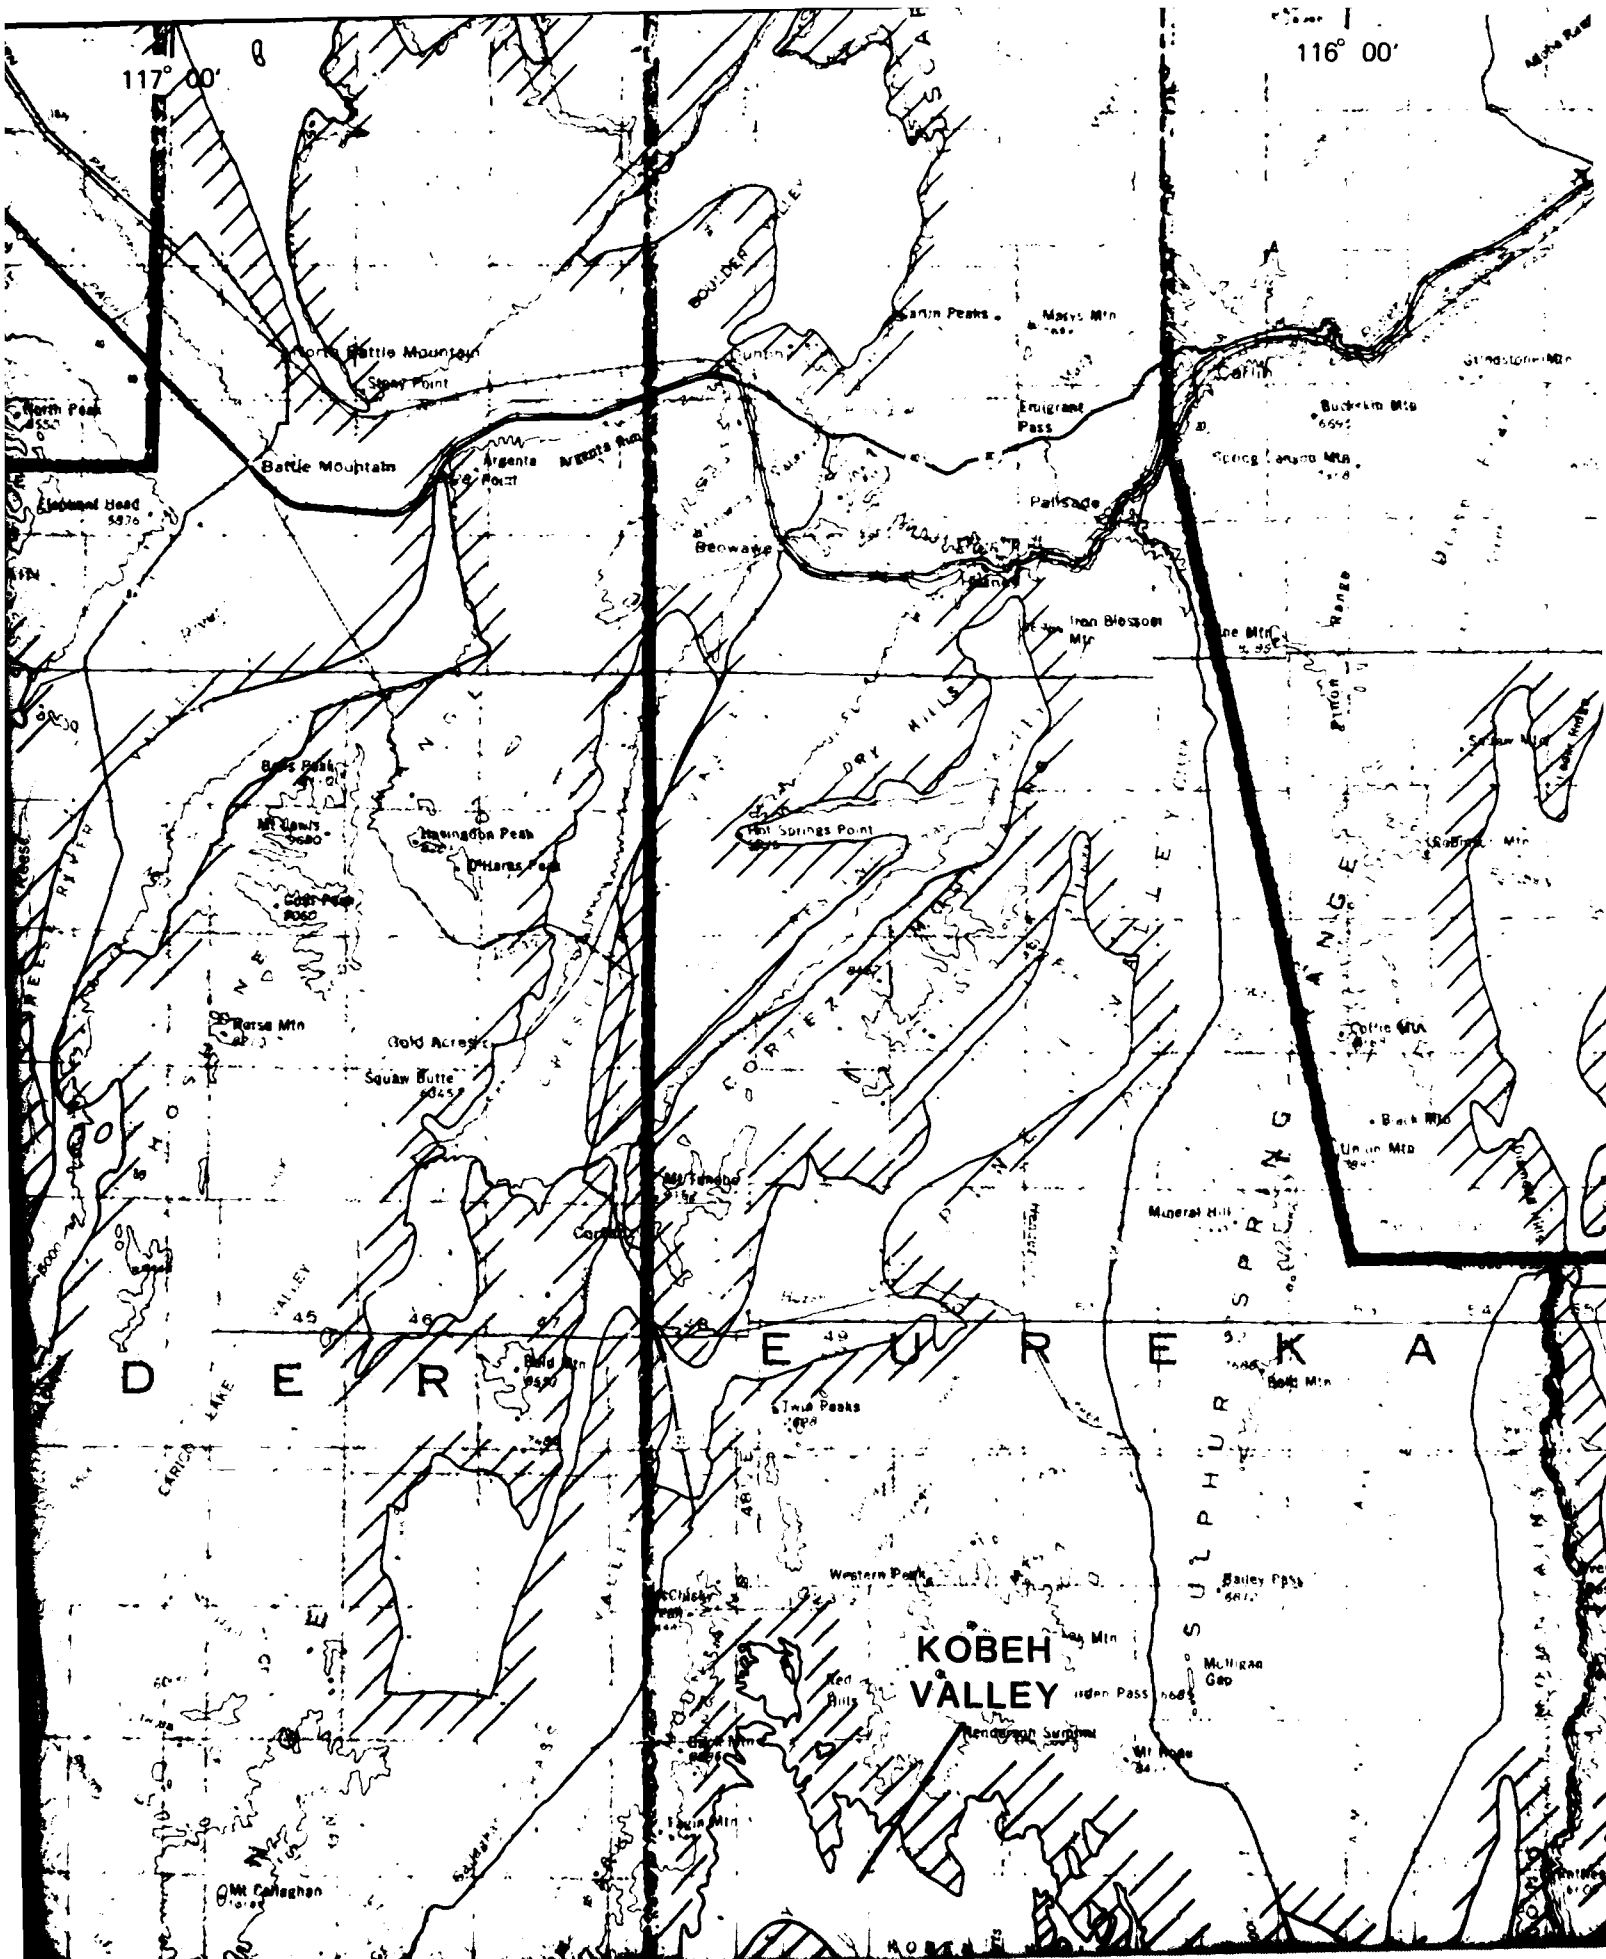

Data obtained from borings, trenches, test pits, seismic refraction lines, and laboratory tests were used to estimate soil properties to a depth of 20 feet (6 m). The data are limited since field activities included only three borings, eight trenches, nine test pits, and 10 seismic refraction lines. There may be soil conditions in the upper 20 feet (6 m) that were not encountered by these 30 data points. The number of

data points available for description of the surficial soils was increased to 62 by using eight surface samples and 24 Cone Penetrometer Test (CPT) soundings to measure in-situ properties.

The soil parameters between a depth of 20 and 100 feet (6 and 30 m) are based on data obtained from only three borings and 10 seismic refraction lines. The spacing between borings ranged from 3.5 to 9 miles (6 to 14 km), therefore, the data presented may not be representative of the entire valley.

The length of the seismic refraction lines was chosen to investigate the velocity profile to a depth of at least 150 feet (46 m), which is the depth of interest for the vertical shelter basing mode.

2.0 RESULTS AND CONCLUSIONS

2.1 SUITABLE AREA

The results of the interpretation of area suitable for deployment in Muleshoe Valley are listed in Table 2-1 and shown in map form in Drawing 2-1. The exclusion criteria used to make this interpretation are discussed in Appendix A2.0.

The total area of basin-fill materials in Muleshoe Valley is 111 square miles (mi^2) (287 square kilometers [km^2]). Thirty-two percent of this area is excluded for the horizontal shelter basing mode, leaving a suitable area of 76 mi^2 (197 km^2). For the vertical shelter basing mode, 35 percent of the total area is excluded, leaving a suitable area of 72 mi^2 (186 km^2). Detailed shelter layout studies show that, with 5200 feet (1585 m) between shelters, three clusters can be placed in Muleshoe Valley.

2.2 BASIN-FILL CHARACTERISTICS

This section contains brief descriptions of the soils in Muleshoe Valley. More detailed information is presented in Sections 3.3 and 3.4.

2.2.1 Surficial Soils

Coarse-grained granular soils are the predominant surficial soils, covering between 90 and 100 percent of the area. They consist of sandy and/or clayey gravels and gravelly, silty and/or clayey sands. Sandy gravels and gravelly sands are predominant in the central and southwestern portions of the valley.

MX SITING INVESTIGATION
DEPARTMENT OF THE AIR FORCE
BMO/AFRC-MX

ESTIMATED SUITABLE AREA
MULESHOE VALLEY, NEVADA

30 JUN 81

TABLE 2-1

In general, surficial soils grade to silty and/or clayey sands going down slope from the valley flanks toward the north-south valley axis. The soils are poorly to well-graded and have variable calcium-carbonate cementation.

Fine-grained soils cover no more than of 10 percent of the area. Typically, they occur along the central axis of the valley. They consist of sandy silts, sandy clays, and silty clays. Their plasticity ranges from nonplastic to slightly plastic.

2.2.2 Subsurface Soils

Soils in the subsurface are also predominantly coarse-grained, consisting of sandy gravels, gravelly sands, sands, silty sands, and clayey sands. Gravels and gravelly sands commonly occur along mountain fronts and grade to finer soils toward the valley axis. The coarse-grained soils are generally dense to very dense below 3 to 4 feet (0.9 to 1.2 m). They are poorly graded on the sides of the valley and well-graded along the axis of the valley. They contain coarse to fine sand and/or gravel, exhibit low compressibilities, and possess moderate to high shear strengths. Fine-grained soils (silts and clays) probably occur in less than 10 percent of the subsurface and are generally restricted to the central and northern portions of the valley. The fine-grained soils are nonplastic to slightly plastic with low to moderate compressibilities and shear strengths. Variable calcium-carbonate cementation exists in all the subsurface soils.

2.3 CONSTRUCTION CONSIDERATIONS

Geotechnical factors and conditions pertaining to construction of the MX system in suitable areas are discussed in this section. Both the horizontal shelter and vertical shelter basing modes are considered.

2.3.1 Grading

Mean surficial slopes in the suitable area are approximately three percent. Surface gradients between five and nine percent are present in about 20 percent of the suitable area. Therefore, preconstruction grading will be minimal for most of the valley. More extensive grading will be necessary along the western and northeastern portions of the valley where surface slopes range from five to nine percent.

The maximum grade at any shelter location in the layout planned for Muleshoe Valley would be between five and nine percent. For approximately 70 percent of the shelters, the grade would be less than five percent.

2.3.2 Roads

Where they are in a dense state, the predominant coarse-grained surficial soils will generally provide good subgrade support for roads. However, most of these soils exhibit low strength to an average depth of 3.3 feet (1.0 m). The subgrade supporting properties of these low-strength, coarse-grained soils are inadequate but they can be improved by mechanical compaction. Compaction to an average depth of 3.5 feet (1.1 m) appears to be

necessary in a majority of the suitable area. Compaction to greater depth may be required in approximately 15 to 25 percent of the granular soil area. Based on results of laboratory CBR tests, the in-situ granular soils, when compacted, will provide good to very good subgrade support for roads.

Fine-grained surficial soils exhibit low strength to an average depth of 13.6 feet (4.1 m), with a maximum depth of 20.0 feet (6.1 m). Supporting qualities of these soils in their natural state are inadequate for direct support of the base or subbase course of the road system. Results of laboratory CBR tests indicate that mechanical compaction will not adequately strengthen these fine-grained soils for direct support of the base course, but a select granular subbase layer over the compacted fine-grained surficial soils will give the required support.

Potential sources of aggregate suitable for use in road base and subbase courses have been identified in Pahroc Valley and are explained in detail in a report of the aggregate resources studies (Ertec, 1981). These studies indicate that aggregates potentially suitable for road construction are available in sufficient quantity in Muleshoe Valley.

Drainage incision depths are generally greater than 6 feet (1.8 m) within 85 to 95 percent of the suitable area. Therefore, the overall cost of drainage structures for roads will be moderate. The depth of incisions of the major drainages along the valley axis ranges from 10 to 25 feet (3.0 to 7.6 m).

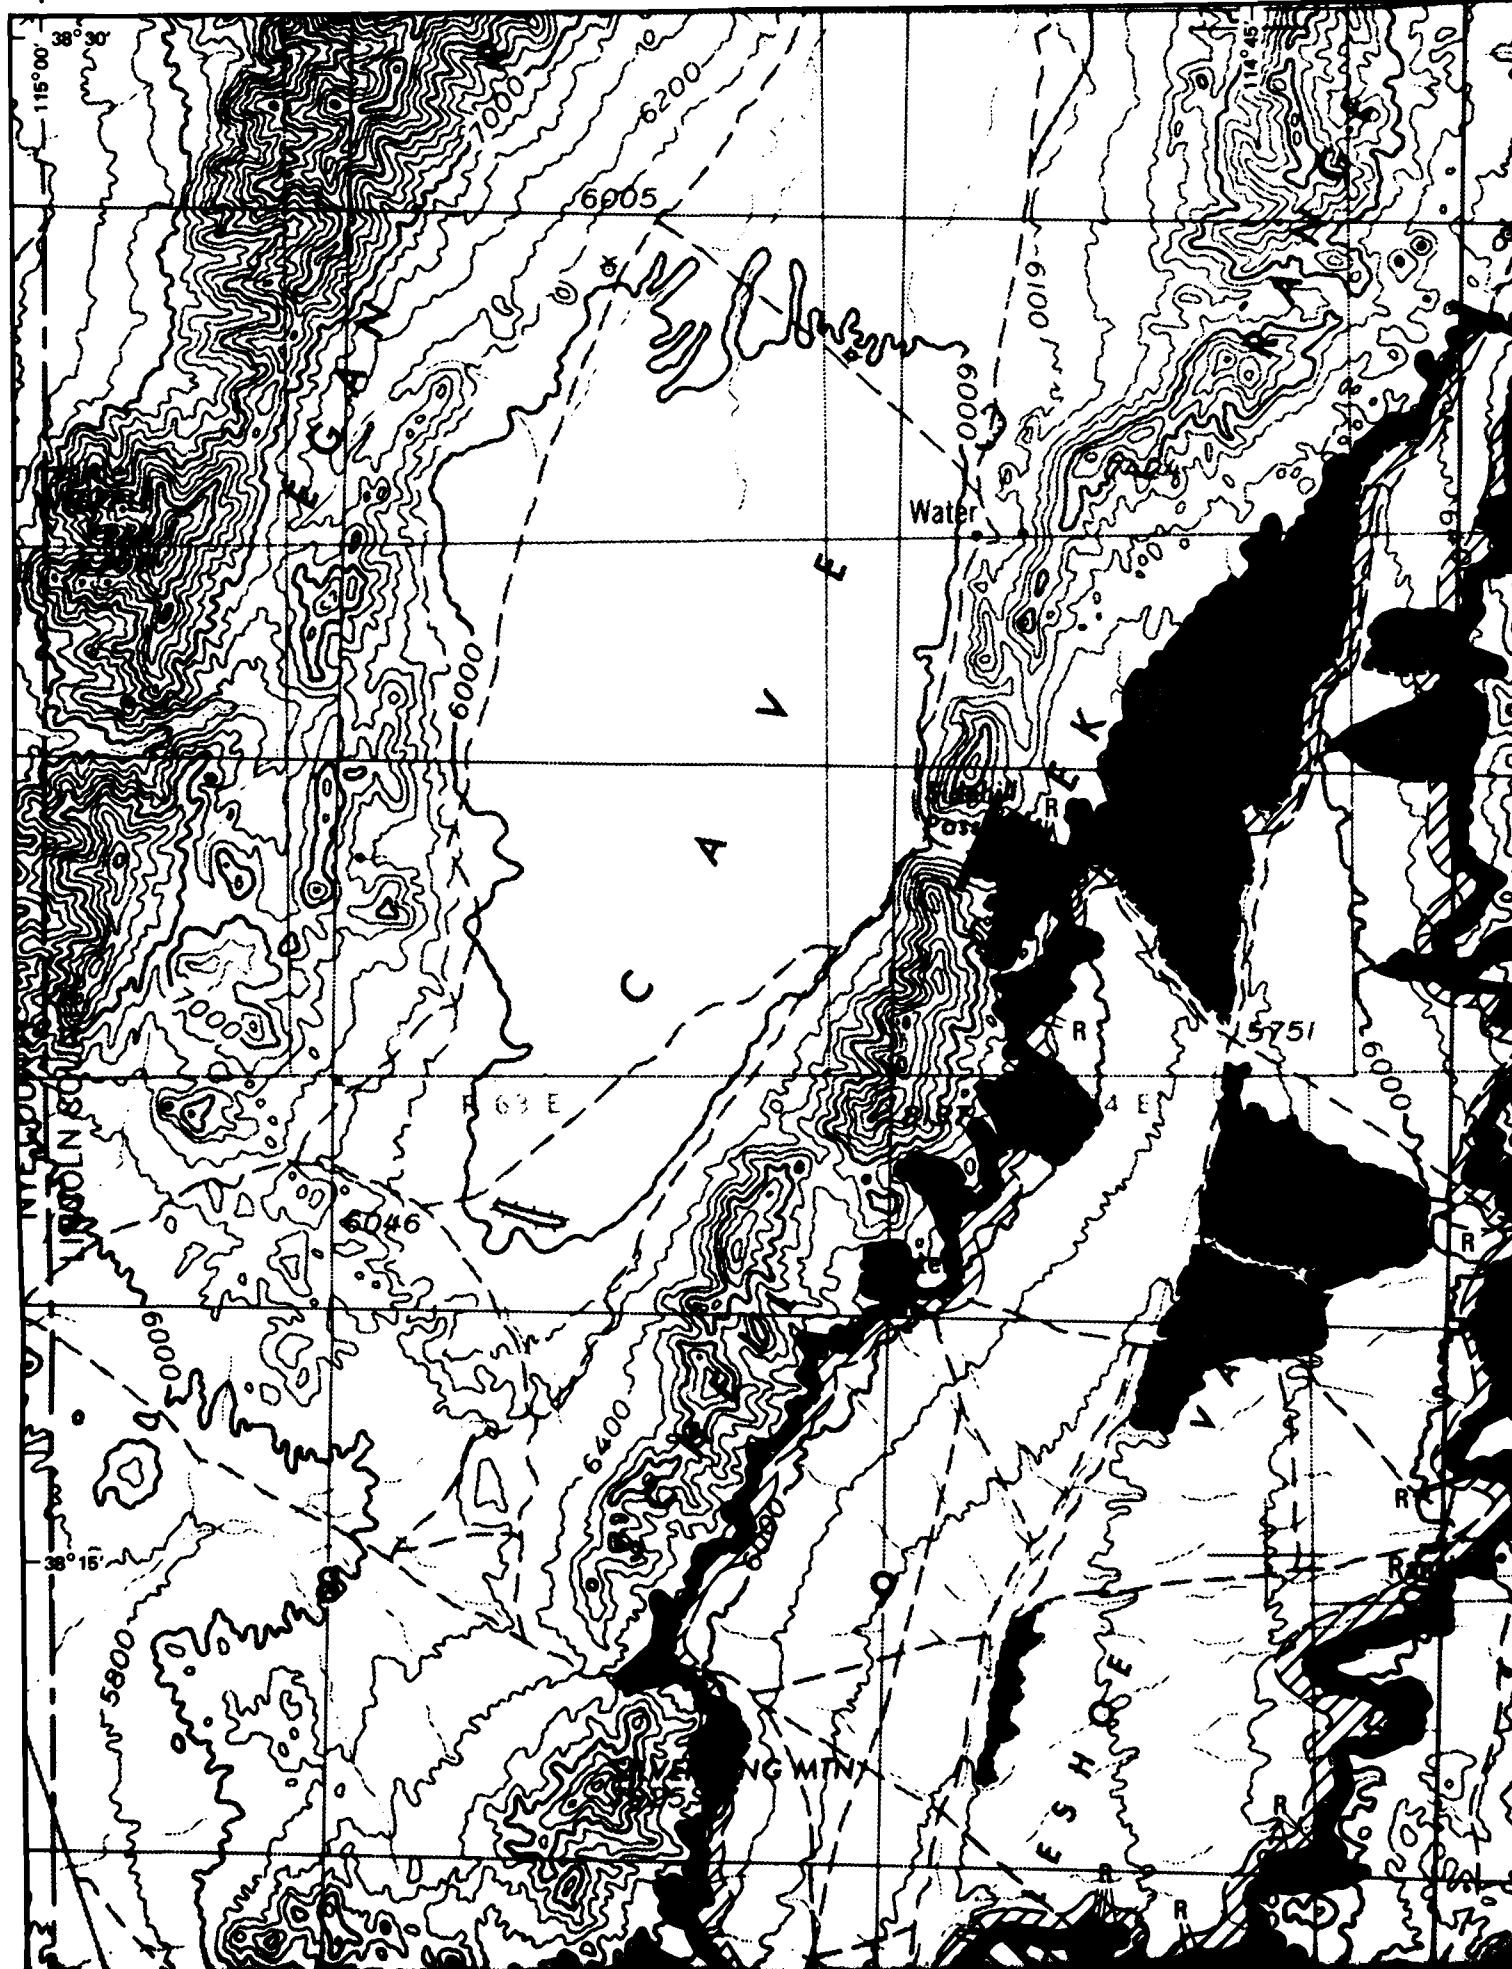

2.3.3 Excavatability and Stability

The soils in the construction zone are generally dense to very dense and possess various degrees of calcium-carbonate cementation.

Horizontal Shelter: Excavation for the horizontal shelter can be done using conventional equipment such as scrapers, backhoes, and bulldozers. Excavation will range from easy to moderately difficult in approximately 65 to 75 percent of the suitable area. However, excavation will be difficult in the remaining area due to cobbles, boulders, and strong calcium-carbonate cementation in the subsurface. Difficult excavation is generally limited to the areas adjacent to the mountain fronts in the vicinity of the central and southwestern portions of the valley. The soils investigation indicates that excavations for construction of shelters should be cut back to slopes ranging from 1/2:1 to 1 1/2:1 (horizontal:vertical) for stability. Variations in density and shear strength, which depend on soil composition and the degree of cementation, cause the wide variation in slope angle. Because of low-strength surficial soil, the top 2 to 4 feet (0.9 to 1.2 m) in all excavations will generally have to be cut back to a flatter slope.

Vertical Shelter: Relatively low compressional wave velocities in the upper 120 feet (36 m) indicate that large diameter auger drills could be used for vertical shelter excavation. Most excavations will be in granular soils with only intermittent cemented or cohesive soil intervals. Therefore, the vertical

walls of these excavations probably will require the use of slurry or other stabilizing techniques in some cases.

3.0 GEOTECHNICAL SUMMARY

3.1 GEOGRAPHIC SETTING

Muleshoe Valley (Figure 3-1) is located in northeastern Lincoln County, Nevada. The valley is bounded on the south by Dry Lake Valley, on the west by the southern portion of the Schell Creek Range, on the north by Lake Valley, and on the east, from north to south, by Dutch John Mountain, Grassy Mountain, and the Fairview Range. Main access to the valley is provided by Sidehill Pass and Cherry Creek Roads. A network of graded roads and jeep trails provide good access throughout the valley. The valley is primarily undeveloped desert rangeland, with scattered corrals, fencing, and water tanks. The Meloy Ranch and reservoir are located on the southeastern edge of the valley at Meloy Springs. Pioche, the nearest town, is approximately 32 miles (52 km) to the southeast.

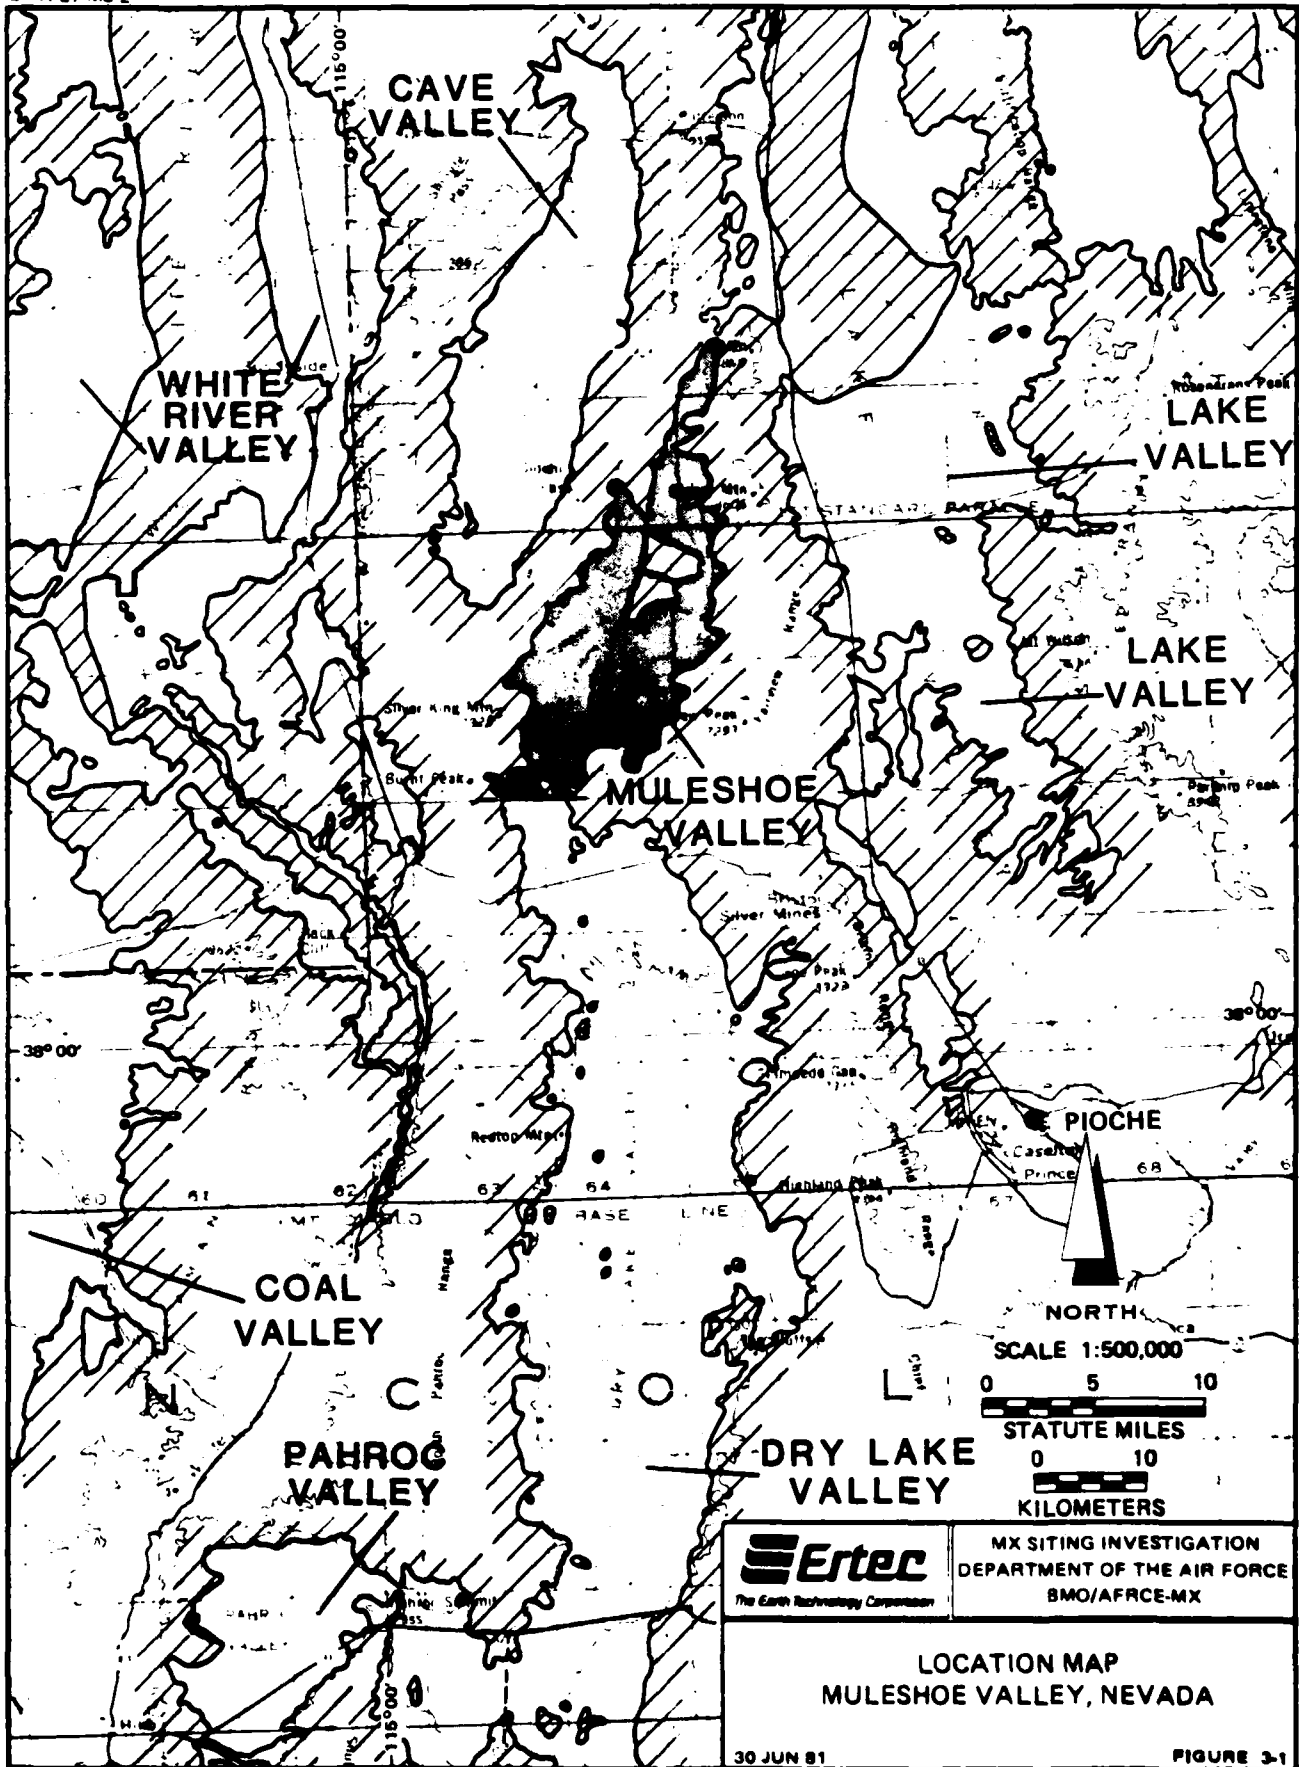

3.2 GEOLOGIC SETTING

Geologic data stops and engineering field activities (Drawing 3-1) were used to verify the aerial photographic interpretation of geologic units.

3.2.1 Rock Types

Muleshoe Valley is a north-northeast trending alluvial basin. The Schell Creek Range to the west consists principally of Paleozoic sedimentary rocks (limestone, dolomite, quartzite, and shale) with some Tertiary volcanic rock (dacite) in the northern portion. The Fairview Range and the eastern bounding mountains consist principally of early Tertiary volcanic rocks overlying

E-TR-27-MS-I

Paleozoic limestone and shale, particularly in the Grassy and Dutch John mountains.

3.2.2 Structure

Muleshoe Valley is part of a small, down-to-the-east tilted block that includes the southern Schell Creek Range. Sediments deposited on the down-tilted, eastern part of the block form the floor of Muleshoe Valley, whereas, the uptilted and emergent western part is the southern Schell Creek Range. A basin bounding fault is present on the east side of the valley and several faults and tectonic lineaments are located to the south (Drawing 3-2). In most cases, the faults have a northerly trend and appear to be normal faults typical of the Great Basin tectonic province.

The basin-bounding fault on the east side of Muleshoe Valley lies at the base of Dutch John Mountain. This fault corresponds to the eastern boundary of the Muleshoe tilt block and is probably responsible for eastward tilting and relative uplift of Dutch John Mountain. The age of this fault is uncertain but is probably Pliocene or younger. A more precise age cannot be determined because young geologic units which would bracket the age are not present over the trace of the fault.

Late Quaternary faults are present at the southwest end of Muleshoe Valley at Silver King Pass. These faults are located north of the intersection of several major, basin-bounding, normal faults at the junction of the Egan, Schell Creek, and North Pahroc ranges (Tschanz and Pampeyan, 1970). The Silver King

Pass faults appear to represent local readjustments to the stresses created at this intersection. They have vertical separations and in places cut Quaternary alluvium.

Although east-trending faults are generally older structural features related to pre-Basin and Range tectonics, Pliocene or younger movement is interpreted on an east-trending fault located about midway between Silver King and Sidehill passes. This fault has strong surface expression as a vegetation alignment on aerial photographs. It apparently has vertical separation.

A local zone of late Quaternary faults and related tectonic lineaments occurs in southern Muleshoe Valley. These features are primarily vegetation lineaments on aerial photographs although the faults have slight topographic relief. Both the faults and lineaments cut intermediate-age alluvial fan deposits (A5i) but are not believed to be major tectonic features because of their limited length and small displacements.

Low hills of volcanic bedrock separate southern Muleshoe Valley from northern Dry Lake Valley. This is reflected in the gravity data for Dry Lake Valley (Fugro National, Inc., 1980) and indicates that the Dry Lake graben is structurally separate from Muleshoe Valley.

3.2.3 Surficial Geologic Units

Alluvial fans of intermediate relative age (A5i) are the predominant surficial geologic unit within the valley (Drawing 3-2). These are composed of sandy gravels and gravelly sands near the

mountain fronts and silty and/or clayey sands near the center of the valley. There is a significant deposit of A5i silty gravel in the southwestern portion of the valley adjacent the drainage axis (Coyote Creek). Old-age alluvial fans are usually located near the mountain fronts but occasionally extend to the axial drainage in the northwestern portion of the valley. Holocene fluvial deposits (A1) are found in the axial drainage.

Surficial geologic units mapped in Muleshoe Valley (Drawing 3-2) consist of the following:

- o Old-Age Alluvial Fan Deposits (A5o) - These Pleistocene age units are fairly extensive within the valley, occupying approximately 19 percent of the total valley area. The fans consist of sandy gravels, gravelly sands, silty sands, and poorly graded sands, generally occurring adjacent to the mountain fronts, although some exist in the central portion of the valley. Cementation ranges from none to strong, generally moderate; caliche development varies mainly from Stage III to IV.
- o Intermediate-Age Alluvial Fan Deposits (A5i) - These fans, also of Pleistocene age, are the most extensive unit within the valley, occupying approximately 77 percent of the valley area. They occur from the base of the mountain fronts to the valley axial drainage. A significant area of the northwestern portion of the valley, and the higher elevations of these fans, are underlain by shallow rock. The unit consists of silty gravels to silty and clayey sands. Cementation varies from absent to strong, generally weak; caliche development varies from none to Stage IV, predominantly Stage II.
- o Young-Age Alluvial Fan Deposits (A5y) - These Holocene sediments occupy less than one percent of the valley area. They occur as small outwash fans primarily along the eastern banks of the axial drainage. The unit consists primarily of silty sand although a few finer-grained fans do exist. Cementation is absent to weak; caliche development varies from none to Stage I.
- o Fluvial and Associated Floodplain Deposits (A1, A2) - These sediments are of Quaternary age and cover approximately three percent of the total area. They occur along the valley axial drainage and in the channels of the major washes. In the northern portion of the valley, the sediments are generally silty and clayey. On the south, the sediments are generally

coarser and represented by poorly graded sands and silty sands. There is generally no cementation; caliche development is none to Stage I.

3.3 SURFACE SOILS

Surficial soils of Muleshoe Valley are predominantly coarse-grained. They range from gravels with traces to some fines to sands with some fines. Fine-grained soils (silts and clays) have a limited areal distribution, being confined generally to the northern washes and central axis of the valley. Soils from the predominant surficial geologic units (those estimated to cover at least five percent of the total area) can be combined into the following three categories based on their physical and engineering characteristics:

1. Sandy gravels, clayey gravels, and gravelly sands (geologic units A5ig, A5is, and A5os);
2. Silty sands and clayey sands (geologic units A5is and A5os); and
3. Sandy silts, sandy clays, and silty clays (geologic units A5os).

3.3.1 Characteristics

A summary of the characteristics of surficial soils, based on field and laboratory test results, is presented in Table 3-1. In addition to the physical properties, the table includes road design data, consisting of laboratory compaction and CBR test results and thicknesses of low-strength surficial soils; and a qualitative assessment of the soils suitability for road use.

Gradation ranges for the three categories of surficial soils are shown in Figure 3-2. The surficial soils in the top 2 feet

FIGURE 3-2

(0.6 m) have sporadic, weak to strong, calcium-carbonate cementation.

Sandy gravels and gravelly sands cover approximately 10 to 20 percent of the total area. Gravelly soils commonly occur in the intermediate-age fans in the southwest portion of the valley and the old alluvial fans in the central portion of the valley. In general, gravel content increases toward the mountain fronts. Gravelly sands and sandy gravels have a wide range of particle sizes, are occasionally well-graded near the central eastern portion of the valley, and contain trace to some fines. Cobbles and boulders to 12 inches (30 cm) and larger in diameter are encountered sporadically at or near the ground surface in these gravelly deposits.

Silty sands and clayey sands are the predominant surficial soils, covering approximately 75 to 85 percent of the total area. They are widely distributed, being the major component in all areas except in the old alluvial fans near mountain fronts and in the fluvial deposits associated with small stream channels in the northern portion of the valley. The sands are coarse to fine and are poorly graded. They contain some amounts of fines and their plasticity ranges from nonplastic to slightly plastic. The fines content is highest along the central axis and decreases toward the valley margin. Gravel content increases toward the mountain fronts.

Silts and clays cover less than 10 percent of the valley area. They consist of sandy silts, sandy clays, and silty clays. They

occur predominantly along the central axis and the washes in the northern portion of the valley. These soils contain trace to some sand. Their plasticity ranges from nonplastic to slightly plastic.

3.3.2 Low-Strength Surficial Soil

Based on the CPT results and soil classifications, the thickness of low-strength surficial soil at each CPT location was estimated and is presented in Table 3-2.

Summaries of the observed range and mean thickness of the low-strength surficial soil for the three categories are included in Table 3-1. Sandy gravels and gravelly sands exhibit low strength to depths ranging from 0.7 to 1.4 feet (0.2 to 0.4 m), with an average of 1.1 feet (0.3 m). Silty and clayey sands exhibit low strengths to depths ranging from 0.9 to 14.0 feet (0.3 to 4.3 m), with an average of 3.8 feet (1.2 m). The range in the thickness of low-strength granular soils is due to variation in the in-situ density and calcium-carbonate cementation. Silts and clays exhibit low strength to depths ranging from 0.5 to 20.0 feet (0.2 to 6.1 m), with an average of 13.6 feet (4.1 m). The variation in the extent of low-strength, fine-grained soils is due to variations in the in-situ density, the amount of fine sand present, and calcium-carbonate cementation.

3.4 SUBSURFACE SOILS

Coarse-grained (granular) soils are estimated to compose more than 90 percent of the subsurface deposits in the upper 100 feet (30 m). These soils consist of sandy gravels, gravelly sands,

sands, silty sands, and clayey sands. Fine-grained soils are mainly encountered along the central axis and are more noticeable in the northern portion. The fine-grained soils consist of sandy silts, sandy clays, and silty clays with plasticity ranging from nonplastic to slightly plastic. Fine-grained soils are estimated to compose less than 10 percent of the subsurface deposits within the total area boundaries.

The composition of subsurface soils with depth, as determined from borings, trenches, and test pits, is illustrated in the soil profiles presented in Figures 3-3 through 3-5. Results of seismic and electrical surveys are summarized in Table 3-3. The characteristics of subsurface soils, determined from field and laboratory tests, are presented in Table 3-4. Ranges of gradation of the subsurface soils are shown in Figure 3-6.

Coarse-grained subsurface soils are poorly to well-graded, contain coarse to fine sands and gravels, and are dense to very dense below 3 to 4 feet (0.9 to 1.2 m). Variable cementation occurs intermittently, but well-developed, continuous cementation was not encountered. These soils exhibit low compressibilities and moderate to high shear strengths.

Fine-grained soils (silts and clays) range in consistency from firm to stiff and exhibit low to moderate compressibilities and shear strengths. Soil plasticity ranges from nonplastic to slightly plastic depending in part on the amount of fine sand present. Calcium-carbonate cementation varies from none to moderate, depending primarily on the age of the deposit.

RANGE OF GRADATION OF
SUBSURFACE SOILS
MULESHOE VALLEY, NEVADA
PAGE 2 OF 2

30 JUN 81

FIGURE 3-6

The soils in the construction zone (120 feet [37 m]) have a wide range of seismic compressional wave velocities (1260 to 6000 fps [384 to 1829 mps]) depending on their composition, consistency, cementation, and moisture content. Seismic compressional wave velocities were measured in only the coarse-grained soils. Generally, velocities in fine-grained soils are found to be substantially lower than those in coarse-grained soils. Compressional wave velocities for deeper materials are also listed in Table 3-3.

Electrical conductivity measured for the soils in the upper 50 feet (15 m) ranged from 0.0034 to 0.0154 mhos per meter (average 0.0101 mhos per meter). At one of the nine measurement locations, the measured conductivities were less than the minimum value of 0.004 mhos per meter specified in the Fine Screening criteria.

Results of chemical tests done on five samples from Muleshoe Valley indicate that potential for sulfate attack for soils on concrete will be "negligible."

3.5 DEPTH TO ROCK

Drawing 3-3 shows the 50- and 150-foot (15- and 46-m) depth-to-rock contours in Muleshoe Valley. This interpretation is based on limited point data from borings, seismic refraction surveys, site-specific published data, and depths inferred from geologic and geomorphic relationships. Approximately 21 percent of the basin-fill material in the valley is interpreted to be underlain by rock at depths of less than 50 feet (15 m). An additional

three percent of the valley is interpreted to be underlain by shallow rock between depths of 50 and 150 feet (15 and 46 m).

The bedrock-fill contact on the western side of the valley is highly irregular with numerous small re-entrant canyons. An area in the northwestern portion of the valley extending from the Schell Creek Range has been interpreted to be underlain by shallow rock. Numerous outcrops of sedimentary and volcanic rocks protrude through the overlying intermediate-age alluvium up to 1 1/2 miles (2.4 km) from the mountain front. Based on these outcrops, the area where rock is interpreted to be at depths of less than 50 feet (15 m) forms a strip varying from one-eighth mile (0.2 km) to 2 miles (3.2 km) in width along the entire western margin of the valley. An outcrop of rock in the south central portion of the valley approximately one-half mile (.8 km) from the mountain front is interpreted to be surrounded by a narrow belt of shallow rock.

The eastern side of the valley is characterized by a moderately to highly irregular mountain front interrupted by long re-entrant canyons. These re-entrant canyons contain alluvial fan or fluvial sediments interpreted to be thin veneers overlying bedrock.

3.6 DEPTH TO WATER

The only source of ground-water data in Muleshoe Valley is a well recorded by the State of Nevada Engineer's Office (Drawing 3-4). The boring was dry to its total depth of about 290 feet (88 m). No ground-water contours are shown in Drawing 3-4

since there are no data to establish the presence of ground water in Muleshoe Valley.

3.7 TERRAIN

3.7.1 Terrain Exclusions

Terrain conditions are shown in Drawing 3-5. Areas designated as terrain exclusions are considered to be unsuitable based on a combination of field-derived and office-derived data which were evaluated under the criteria in Appendix Table A2-1. Field derived exclusions include: 1) areas having very steep slopes, such as the sides of major drainages; and 2) areas in which incisions deeper than 10 feet (3 m) are spaced closer than 1000 feet (305 m) apart. Office-derived exclusions consist primarily of identifying areas on topographic maps that have slopes greater than 10 percent. In some instances, where road access is inadequate for field inspection, office analysis of aerial photographs was used to define and exclude areas of rugged or adverse terrain. However, preference was given to determining such exclusions in the field. Even though areas where slopes exceed five percent are considered to be suitable for deployment, they are shown in Drawing 3-5 because they require special consideration in planning construction and operations.

Several portions of Muleshoe Valley are excluded based on the terrain criteria. Areas of terrain exclusions on the eastern side of the valley border deeply-incised major tributaries. In the central part of the valley, the axial drainage (Coyote Wash) is partially bordered by similar exclusions. Most of these

terrain exclusion areas are based on the incision depth-spacing criteria (field determined). Some areas in the northeasternmost and southwesternmost portions of the valley are excluded based upon the 10 percent slope exclusion criteria.

3.7.2 Incision Depths and Number of Drainages Per Mile

Data on incision depths and number of drainages encountered per mile were analyzed for Muleshoe Valley. Information on incision depths was obtained from field observations; the number of drainages per mile was determined from both field observations and interpretation of aerial photographs.

The results shown in Table 3-5 are average values of the two drainage characteristics (depth and number per mile). They are listed for each prevalent surficial unit with further breakdowns providing data on 1) characteristics in the unit on each side of the valley axial drainage and 2) characteristics of the unit where its surface slopes are between five and 10 percent versus areas where its slopes are less than five percent.

The small areal extent of some of the surficial units resulted in limited or insufficient data for analysis (Table 3-5). The available data show the intermediate-age fan unit (A5i) has the greatest number of drainages per mile and the deepest incision depths. Drainages are typically deeper in this unit on the eastern side of the valley than on the western side, but are more numerous on the western side. Incision depths vary within the different geomorphic units depending upon grain size of the unit and the degree of surface slope.

APPENDIX

A1.0 GLOSSARY OF TERMS

ACTIVE FAULT - A fault which has had surface displacement within Holocene time (about the last 11,000 years).

ACTIVITY NUMBER - A designation composed of the valley abbreviation followed by the activity type and a unique number; may also be used to designate a particular location in a valley.

ALLUVIAL FAN - A body of stream deposits whose surface approximates a segment of a cone that radiates downslope from the point where the stream leaves a mountainous area and experiences a marked change in gradient resulting in deposition of alluvium.

ALLUVIUM - A general term for a more-or-less stratified deposit of gravel, sand, silt, clay, or other debris, moved by streams from higher to lower ground.

AQUIFER - A permeable saturated zone below the earth's surface capable of conducting and yielding water as to a well.

ARRIVAL - An event; the appearance of seismic energy on a seismic record; a lineup of coherent energy signifying the arrival of a new wave train.

ATTERBERG LIMITS - A general term applied to the various tests used to determine the various states of consistency of fine-grained soils. The four states of consistency are solid, semisolid, plastic, and liquid.

Liquid limit (LL) - The water content corresponding to the arbitrary limit between the liquid and plastic states of consistency of a soil (ASTM D 423-66).

Plastic limit (PL) - The water content corresponding to an arbitrary limit between the plastic and the semisolid states of consistency of a soil (ASTM D 424-59).

Plasticity index (PI) - Numerical difference between the liquid limit and the plastic limit indicating the range of moisture content through which a soil-water mixture is plastic.

BASIN-FILL MATERIAL/BASIN-FILL DEPOSITS - Heterogeneous detrital material deposited in a sedimentary basin.

BASE LEVEL - The theoretical limit or lowest level toward which erosion constantly progresses; the level at which neither erosion nor deposition takes place.

- BEDROCK** - A general term for the rock, usually solid, that underlies soil or other unconsolidated, surficial material. The term is also used here to include the rock composing the local mountain ranges.
- BORING** - A hole drilled in the ground for the purpose of sub-surface exploration.
- BOUGUER ANOMALY** - The residual value obtained after latitude, elevation, and terrain corrections have been applied to gravity data.
- BOULDER** - A rock fragment, usually rounded by weathering and abrasion with an average diameter of 12 inches (305 mm) or more.
- BULK SAMPLE** - A disturbed soil sample (bag sample) obtained from cuttings brought to the ground surface by a drill rig auger or obtained from the walls of a trench excavation.
- c** - Cohesion (Shear strength of a soil not related to interparticle friction).
- CALCAREOUS** - Containing calcium carbonate; presence of calcium carbonate is commonly identified on the basis of reaction with dilute hydrochloric acid.
- CALICHE** - In general, secondary calcium carbonate cementation of unconsolidated materials occurring in arid and semiarid areas.
- CALIFORNIA BEARING RATIO (CBR)** - The ratio (in percent) of the resistance to penetration developed by a subgrade soil to that developed by a specimen of standard crushed rock base material (ASTM D 1883-73). During the CBR test, the load is applied on the circular penetration piston (3 inches² base area [19 cm²]) which is penetrated into the the soil sample at a constant penetration rate of 0.05 inch/minute (1.2 mm/min). The bearing ratio reported for the soil is normally the one at 0.1 inch (2.5 mm) penetration.
- CLAST** - An individual constituent, grain, or fragment of a sediment or rock, produced by the mechanical weathering (disintegration) of a larger rock mass.
- CLAY** - Fine-grained soil (passes No. 200 sieve [0.074 mm]) that can be made to exhibit plasticity within a range of water contents and that exhibits considerable strength when air-dried.
- CLAY SIZE** - That portion of the soil finer than 0.002 mm.
- CLOSED BASIN** - A catchment area draining to some depression or lake within its area from which water escapes only by evaporation or infiltration into the subsurface.

COARSE-GRAINED (or granular) - A term which applies to a soil of which more than one-half of the soil particles, by weight, are larger than 0.074 mm in diameter (No. 200 U.S. sieve size).

COARSER-GRAINED - A term applied to alluvial fan deposits which are predominantly composed of material (cobble) larger than 3 inches (76 mm) in diameter.

COBBLE - A rock fragment, larger than a pebble and smaller than a boulder, having a diameter between 3 and 10 inches (64 and 256 mm), being somewhat rounded or otherwise modified by abrasion in the course of transport.

COMPACTION TEST - A test to determine the relationship between the moisture content and density of a soil sample which is prepared in compacted layers at various water contents (ASTM D 1557-70).

COMPRESSIBILITY - Property of a soil pertaining to its susceptibility to decrease in volume when subjected to load.

COMPRESSIONAL WAVE - An elastic body wave in which particle motion is in the direction of propagation: the type of seismic wave assumed in conventional seismic exploration. Also called P-wave, dilatational wave, and longitudinal wave.

CONDUCTIVITY - The ability of a material to conduct electrical current. In isotropic material, conductivity is the reciprocal of resistivity. Units are mhos per meter.

CONE PENETROMETER TEST - A method of evaluating the in-situ engineering properties of soil by measuring the penetration resistance developed during the steady slow penetration of a cone (60° apex angle, 10-cm² projected area) into soil.

Cone resistance or end bearing resistance, q_c - The resistance to penetration developed by the cone, equal to the vertical force applied to the cone divided by its horizontally projected area.

Friction resistance, f_s - The resistance to penetration developed by the friction sleeve, equal to the vertical force applied to the sleeve divided by its surface area. This resistance consists of the sum of friction and adhesion.

Friction ratio, f_R - The ratio of friction resistance to cone resistance, f_s/q_c , expressed in percent.

CONSISTENCY - The relative ease with which a soil can be deformed.

CONSOLIDATION TEST - A type of test to determine the compressibility of a soil sample. The sample is enclosed in the consolidometer which is then placed in the loading device. The load is applied in increments at certain time intervals and the change in thickness is recorded.

CORE SAMPLE - A cylindrical sample obtained with a rotating core barrel with a cutting bit at its lower end. Core samples are obtained from indurated deposits and in rock.

DEGREE OF SATURATION - Ratio of volume of water in soil to total volume of voids.

DIRECT SHEAR TEST - A type of test to measure the shear strength of a soil sample where the sample is forced to fail on a predetermined plane.

DISSECTION/DISSECTED (alluvial fans) - The cutting of stream channels into the surface of an alluvial fan by the movement (or flow) of water.

DRY UNIT WEIGHT/DRY DENSITY - Weight per unit volume of the solid particles in a soil mass.

ELECTRICAL CONDUCTIVITY - Ability of a material to conduct electrical current.

ELECTRICAL RESISTIVITY - Property of a material which resists flow of electrical current.

EOLIAN - A term applied to materials which are deposited by wind.

EPHEMERAL (stream) - A stream or reach of a stream that flows briefly only in direct response to precipitation in the immediate locality, and whose channel is at all times above the water table.

EXTERNAL DRAINAGE - Stream drainage system whose down-gradient flow is unrestricted by any topographic impediments.

EXTRUSIVE ROCK - Igneous rock that has been ejected onto the earth's surface (e.g., lava, basalt, rhyolite, andesite, detrital material, volcanic tuff, pumice).

FAULT - A plane or zone of fracture along which there has been displacement.

FAULT BLOCK MOUNTAINS - Mountains that are formed by normal faulting in which the surface crust is divided into partially to entirely fault-bounded blocks of different elevations.

FINE-GRAINED - A term which applies to a soil of which more than one-half of the soil particles, by weight, are smaller than 0.074 mm in diameter (passing the No. 200 U.S. size sieve).

FINER-GRAINED - A term applied to alluvial fan deposits which are composed predominantly of material less than 3 inches (76 mm).

FLUVIAL DEPOSITS - Material produced by river action; generally loose, moderately well-graded sands and gravel.

FORMATION - A mappable assemblage of rocks characterized by some degree of homogeneity or distinctiveness.

FUGRO DRIVE SAMPLE - A 2.50-inch-(6.4-cm) diameter soil sample obtained from a drill hole with a Fugro drive sampler. The Fugro drive sampler is a ring-lined barrel sampler containing 12 one-inch-(2.54-cm) long brass sample rings. The sampler is advanced into the soil using a drop hammer.

GEOMORPHOLOGY - The study, classification, description, nature, origin, and development of present landforms and their relationships to underlying structures and of the history of geologic changes as recorded by these surface features.

GEOPHONE - The instrument used to transform seismic energy into electrical voltage; a seismometer, jug, or pickup.

GRABEN - An elongated crustal block that has been downthrown along faults relative to the rocks on either side.

GRAIN-SIZE ANALYSIS (GRADATION) - A type of test to determine the distribution of soil particle sizes in a given soil sample. The distribution of particle sizes larger than 0.074 mm (retained on the No. 200 sieve) is determined by sieving, while the distribution of particle sizes smaller than 0.074 mm is determined by a sedimentation process using a hydrometer.

GRANULAR - See Coarse-Grained.

GRAVEL - Particles of rock that pass a 3-inch (76.2 mm) sieve and are retained on a No. 4 (4.75 mm sieve).

GRAVITY - The force of attraction between bodies because of their mass. Usually measured as the acceleration of gravity.

GYPSIFEROUS - Containing gypsum, a mineral consisting mostly of calcium sulfate.

HORST - An elongated crustal block that has been uplifted along faults relative to the rocks on either side.

INTERIOR DRAINAGE - Stream drainage system that flows into a closed topographic low (basin).

INTRUSIVE (rock) - A rock formed by the process of emplacement of magma (liquid rock) in preexisting rock, (e.g., granite, granodiorite, quartz monzonite).

LACUSTRINE DEPOSITS - Materials deposited in a lake environment.

LINE - A linear array of observation points, such as a seismic line.

LINEAMENT - A linear topographic feature of regional extent that is thought to reflect crustal structure.

LIQUID LIMIT - See ATTERBERG LIMITS.

LOW STRENGTH SURFICIAL SOIL - Soil which will perform poorly as a road subgrade at its present consistency when used directly beneath a road section.

MOISTURE CONTENT - The ratio, expressed as a percentage, of the weight of water contained in a soil sample to the oven-dried weight of the sample.

N VALUE - Penetration resistance, described as the number of blows required to drive the standard split-spoon sampler for the second and third 6 inches (0.15 m) with a 140-pound (63.5-kg) hammer falling 30 inches (0.76 m) (ASTM D 1586-67).

OPTIMUM MOISTURE CONTENT - Moisture content at which a soil can be compacted to a maximum dry unit weight by a given compactive effort.

P-WAVE - See Compressional Wave.

PATINA (Desert Varnish) - A dark coating or thin outer layer produced on the surface of a rock or other material by weathering.

PAVEMENT/DESERT PAVEMENT - When loose material containing pebble-sized or larger rocks is exposed to rainfall and wind action, the finer dust and sand are blown or washed away and the pebbles gradually accumulate on the surface, forming a mosaic which protects the underlying finer material from wind attack. Pavement can also develop in finer-grained materials. In this case, the armored surface is formed by dissolution and cementation of the grains involved.

PERCHED GROUND WATER - Unconfined ground water separated from an underlying main body of ground water by an unsaturated zone.

PERMEABILITY - The property of soil and/or rock material which permits liquid to pass through.

pH - An index of the acidity or alkalinity of a soil in terms of the logarithm of the reciprocal of the hydrogen ion concentration.

PHI (\emptyset) - Angle of internal friction.

PIEZOMETRIC SURFACE - An imaginary surface representing the static head of ground water and defined by the level to which water will rise in a well.

PITCHER TUBE SAMPLE - An undisturbed, 2.87-inch- (73-mm) diameter soil sample obtained from a drill hole with a Pitcher tube sampler. The primary components of this sampler are an outer rotating core barrel with a bit and an inner stationary, spring-loaded, thin-wall sampling tube which leads or trails the outer barrel drilling bit depending upon the hardness of the material being penetrated.

PLASTIC LIMIT - See ATTERBERG LIMITS.

PLASTICITY INDEX - See ATTERBERG LIMITS.

PLAYA/PLAYA DEPOSITS - A term used in the southwest U.S. for a dried-up, flat-floored area composed of thin, evenly stratified sheets of clay, silt, or fine sand, and representing the lowest part of a shallow, completely closed or undrained, desert lake basin in which water accumulates and is quickly evaporated, usually leaving deposits of soluble salts.

POORLY GRADED - A descriptive term applied to a coarse-grained soil if it consists predominantly of one particle size (uniformly graded) or has a wide range of sizes with some intermediate sizes obviously missing (gap-graded).

RANGE-BOUNDING FAULT - Usually a normal fault in which one side has moved up relative to the other and which separates the mountain front from the valley.

RELATIVE AGE - The relationship in age (oldest to youngest) between geologic units without specific regard to number of years.

RESISTIVITY (True, Intrinsic) - The property of a material which resists the flow of electric current. The ratio of electric-field intensity to current density.

ROCK UNITS - Distinct rock masses with different characteristics (e.g., igneous, metamorphic, sedimentary).

ROTARY WASH DRILLING - A boring technique in which advancement of the hole through overburden is accomplished by rotation of a heavy string of rods while continuous downward pressure is maintained through the rods on a bit at the bottom of the hole. Water or drilling mud is forced down the rods to the bit, and the return flow brings the cuttings to the surface.

S-WAVE - See Shear Wave.

SAND - Soil passing through No. 4 (4.75 mm) sieve and retained on No. 200 (0.075 mm) sieve.

SAND DUNE - A low ridge or hill consisting of loose sand deposited by the wind, found in various desert and coastal regions and generally where there is abundant surface sand.

SEISMIC - Having to do with elastic waves. Energy may be transmitted through the body of an elastic solid as P-waves (compressional waves) or S-waves (shear waves).

SEISMIC LINE - A linear array of travel time observation points (geophones). In this study, each line contains 24 geophone positions.

SEISMIC REFRACTION DATA: - Data derived from a type of seismic shooting based on the measurement of seismic energy as a function of time after the shot and of distance from the shot, by determining the arrival times of seismic waves which have traveled nearly parallel to the bedding in high-velocity layers in order to map the depth to such layers.

SEISMOGRAM - A seismic record.

SEISMOMETER - See Geophone.

SHEAR STRENGTH - The maximum resistance of a soil to shearing (tangential) stresses.

SHEAR WAVE - A body wave in which the particle motion is perpendicular to the direction of propagation. Also called S-Wave or transverse wave.

SHEET FLOW - A process in which stormborne water spreads as a thin, continuous veneer (sheet) over a large area.

SHEET SAND - A blanket deposit of sand which accumulates in shallow depressions or against rock outcrops, but does not have characteristic dune form.

- SHOT - Any source of seismic energy; e.g., the detonation of an explosive.
- SHOT POINT - The location of any source of seismic energy; e.g., the location where an explosive charge is detonated in one hole or in a pattern of holes to generate seismic energy. Abbreviated SP.
- SILT - Fine-grained soil passing the No. 200 sieve (0.074 mm) that is nonplastic or very slightly plastic and that exhibits little or no strength when air-dried.
- SILT SIZE - That portion of the soil finer than 0.02 mm and coarser than 0.002 mm.
- SITE - Location of some specific activity or reference point.
- SPECIFIC GRAVITY - The ratio of the weight in air of a given volume of soil solids at a stated temperature to the weight in air of an equal volume of distilled water at a stated temperature.
- SPLIT-SPOON SAMPLE - A disturbed sample obtained with a split-spoon sampler with an outside diameter of 2.0 inches (5.1 cm). The sample consists of a split barrel which is driven into the soil using a drop hammer.
- SPREAD - The layout of geophone groups from which data from a single shot are recorded simultaneously. Spreads containing 24 geophones have been used in Fugro's seismic refraction surveys.
- STREAM CHANNEL DEPOSITS - See Fluvial Deposits.
- STREAM TERRACE DEPOSITS - Stream channel deposits no longer part of an active stream system, generally loose, moderately well graded sand and gravel.
- SULFATE ATTACK - The process during which sulfates, salts of sulfuric acid, contained in ground water cause dissolution and damage to concrete.
- SURFICIAL DEPOSIT - Unconsolidated residual colluvial and alluvial deposits occurring on or near the earth's surface.
- TEST PIT - An excavation made to depths of about 5 feet (1.5 m) by a backhoe. A test pit permits visual examination of undisturbed material in place.
- TRENCH - An excavation by a backhoe to depths of about 15 feet (4.5 m). A trench permits visual examination of soil in place and evaluation of excavation wall stability.

TRIAXIAL COMPRESSION TEST - A type of test to measure the shear strength of an undisturbed soil sample (ASTM D2850-70). To conduct the test, a cylindrical specimen of soil is surrounded by a fluid in a pressure chamber and subjected to an isotropic pressure. An additional compressive load is then applied, directed along the axis of the specimen called the axial load.

Consolidated-drained (CD) Test - A triaxial compression test in which the soil was first consolidated under an all-around confining stress (test chamber pressure) and was then compressed (and hence sheared) by increasing the vertical stress. Drained indicates that excess pore water pressures generated by strains are permitted to dissipate by the free movement of pore water during consolidation and compression.

Consolidated-undrained (CU) Test - A triaxial compression test in which essentially complete consolidation under the confining (chamber) pressure is followed by a shear at constant water content.

UNCONFINED COMPRESSION - A type of test to measure the compressive strength of an undisturbed sample (ASTM D 2166-66). Unconfined compressive strength is defined as the load per unit area at which an unconfined prismatic or cylindrical specimen of soil will fail in a simple compression test.

UNIFIED SOIL CLASSIFICATION SYSTEM (USCS) - A system which determines soil classification for engineering purposes on the basis of grain-size distribution and Atterberg limits.

VALLEY FILL - See Basin-Fill Material/Basin-Fill Deposits.

VELOCITY - Refers to the propagation rate of a seismic wave without implying any direction. Velocity is a property of the medium and not a vector quantity when used in this sense.

VELOCITY LAYER - A layer of rock or soil with a homogeneous seismic velocity.

VELOCITY PROFILE - A cross section showing the distribution of material seismic velocities as a function of depth.

WASH SAMPLE - A sample obtained by screening the returned drilling fluid during rotary wash drilling.

WATER TABLE - The upper surface of an unconfined body of water at which the pressure is equal to the atmospheric pressure.

WELL-GRADED - A soil is identified as well-graded if it has a wide range in grain size and substantial amounts of most intermediate sizes.

A2.0 EXCLUSION CRITERIA

The exclusion criteria used during the Verification Studies are based on both geotechnical and cultural considerations. Land excluded for geotechnical reasons includes areas of shallow rock, shallow water, and adverse terrain. Cultural exclusions include areas near towns, lands already withdrawn from public use, and regions with potentially high economic value. The exclusion criteria are defined in Table A2-1.

E-TR-27-MS-I

<u>CRITERIA</u>		<u>DEFINITION AND COMMENTS</u>
SURFACE ROCK AND ROCK OCCUR- RING WITHIN 50 FEET (15m) AND 150 FEET (46m) OF THE GROUND SURFACE		Rock is defined as any earth material which is not rippable by conventional excavation methods. Where available, seismic P-wave velocities were evaluated in the determination of rock conditions.
SURFACE WATER AND GROUND WATER OCCURRING WITHIN 50 FEET (15m) AND 150 FEET (46m) OF THE GROUND SURFACE		Surface water includes all significant lakes, reservoirs, swamps, and major perennial streams. Water which would be encountered in a 50-foot and 150-foot excavation was considered in the application of this criterion. Depths to ground water resulting from deeper confined aquifers were not considered.
TERRAIN	Percent Grade	Areas having surface gradients exceeding 10 percent or a preponderance of slopes exceeding 10 percent as determined from maps at scales of 1 :125 000, 1 :62 500, and 1 :24 000 and by field observation.
	Drainage	Areas averaging two or more 10-foot deep drainages per 1000 feet (measured parallel to contours, as determined from maps at scales of 1 :24,000 or in the field).
CULTURAL	Quantity/Distance:	Eighteen nautical mile exclusion arcs from cities having populations (1970) of 25,000 or more. Three nautical mile exclusion arcs from cities having populations (1970) of between 5,000 and 25,000.
	Land Use:	All significant federal and state forests, parks, monuments, and recreational areas. All significant federal and wildlife refuges, grasslands, ranges, preserves and management areas. Indian reservations.

TABLE A2-1

A3.0 ENGINEERING GEOLOGIC PROCEDURES

The principal objectives of the field geology investigation were to:

1. Delineate surficial extent of soil types and geologic units;
2. Assess terrain conditions; and
3. Make observations helpful in refining depth to rock and water.

Aerial photographs (1:60,000 scale black and white; 1:25,000 scale color) served as the base on which all mapping was done. Field activities were directed toward checking the photogeologic mapping.

Field checking consisted chiefly of collecting data about surficial soils at selected locations in order to refine contacts and define engineering characteristics of photogeologic units. At each location, observations of grain-size distribution, color, clast lithology, surface soil development, and a variety of engineering parameters were recorded (see Volume II, Geotechnical Data). Observations were made in existing excavations (borrow pits, road cuts, stream cuts) or in hand-dug test pits. Extrapolation of this data, to determine surficial extent, was accomplished by geologic reconnaissance over existing roads.

Of the parameters listed, grain size is the most important for engineering purposes and, for this reason, is included in the geologic unit designation. However, grain size is not readily mapped on aerial photos, and much of the field work involved determination of the extent of surficial deposits of a particular grain-size category (gravel, sand, or fine-grained).

Terrain data were also taken at geologic field stations. Drainage width and depth were estimated and predominant surface slope was measured. Slopes were measured over a distance of 100 to 150 feet (31 to 46 m) with an Abney hand level. For additional data, depths of major drainages encountered during geologic reconnaissance between stations were recorded on the aerial photographs.

To help refine depth to rock interpretations, observations were concentrated along the basin margin to identify areas of shallow rock. Observations regarding depth to water were restricted to measurements in existing wells and identification of areas with water at the surface.

A4.0 GEOPHYSICAL PROCEDURES

A4.1 SEISMIC REFRACTION SURVEYS

A4.1.1 Instruments

Field explorations were performed with a 24-channel SIE Model RS-44 seismic refraction system which consisted of 24 amplifiers coupled with a dry-write, galvanometer-type recording oscillograph. Seismic energy was detected by Mark Products Model L-10 geophones with natural frequency of 4.5 Hz. Geophones were fitted with short spikes to provide good coupling with the ground. Cables with two takeout intervals were used to transmit the detected seismic signal from the geophones to the amplifiers. Time of shot was transmitted from shotpoint to recording system via an FM radio link.

The degree of gain was set on the amplifiers by the instrument operators and was limited by the background noise at the time of the shot. The amplifiers are capable of maximum gain of 1.1 million. The oscillograph placed timing lines on the seismograms at 0.01-second intervals. The timing lines form the basis for measuring the time required for the energy to travel from the shot to each geophone.

A4.1.2 Field Procedures

Each seismic refraction line consisted of a single spread of 24 geophones with a distance of 410 feet (125 m) between end points. Geophone spacing provided six intervals of 25 feet (7.6 m) at both ends of the line and 11 central intervals of 10 feet (3 m). Six shots were made per spread at locations 65 feet (20 m), 190 (58 m), and 305 feet (93 m) left and right of the spread center. The recording system was located between geophones 12 and 13.

The explosive used was "Kinestik" which was transported to the site as two nonexplosive components, a powder and a liquid. The components were mixed in the field to make an explosive compound. Charges ranged in size from one-third to five pounds and were buried from 1 to 5 feet (0.3 to 1.5 m) deep. Charges were detonated using Reynold's exploding bridge wire (EBW) detonators instead of conventional electric blasting caps. Use of EBWs provides maximum safety against accidental detonation and extremely accurate "time breaks" (instant of detonation). Relative elevations of geophones and shotpoints were obtained by level or transit where lines had more than 2 or 3 feet (0.6 to 0.9 m) of relief.

A4.1.3 Data Reduction

The travel times for compressional waves from the shots to the geophones were obtained from the seismograms by visual inspection. These times were plotted at their respective horizontal

distances and best fit lines were drawn through the points to obtain apparent velocities for materials below the seismic line.

A combination of delay time and ray tracing methods was used in a computer program to obtain depth to refracting horizons from the time-distance information.

A4.2 ELECTRICAL RESISTIVITY SURVEYS

A4.2.1 Instruments

Electrical resistivity measurements were made with a Bison Instrument model 2350B resistivity meter which provides current to the earth through two electrodes and measures the potential (voltage) drop across two other electrodes.

A4.2.2 Field Procedures

Electrical resistivity soundings were made using the Schlumberger electrode arrangement. Soundings are made by successive resistivity measurements which obtain information from deeper and deeper materials. The depth of penetration of the electrical current is made greater by increasing the distance between the current electrodes. The arrangement of electrodes in the Schlumberger method is shown in Figure A4-1. The four electrodes are in a line with the two current electrodes on the ends. The distance between the current electrodes (AB) is always five or more times greater than the distance between the potential electrodes (MN).

The initial readings are made with MN equal to 5 feet (1.5 m) and AB equal to 30 feet (9 m). Successive readings were made with AB at 40, 50, 60, 80, 100, 120, 160, 200, 300, 400, 500, and 600 feet (12, 15, 18, 24, 30, 37, 49, 61, 91, 122, 152, and 183 m). MN spacing is sometimes increased one or two times as AB is expanded. This increase is required when the signal drops to a level below the meter's sensitivity. The potential drop is greater between more widely spaced electrodes (MN), so increasing MN increases the signal. When it becomes necessary to increase MN, the spacing of AB is reduced to the spacing of the previous reading. MN is then increased, and a measurement is made. This provides two resistivity measurements at the same AB spacing but with different MN spacings.

A4.2.3 Data Reduction

Each apparent resistivity value is plotted versus one-half the current electrode spacing ($AB/2$) used to obtain it. Log-log graph paper is used to form the coordinates for the graph. A smooth curve is drawn through the points. This sounding curve forms the basis for interpreting the resistivity layering at the sounding location.

FIGURE A4.1

A computer program that does iterative "curve-matching" is used to develop a layer model that has a theoretical resistivity curve that is similar to the field curve. Input to the program is generated by digitizing the field curve with an electronic digitizer.

A5.0 ENGINEERING PROCEDURES

Soil engineering activities consisted of the following:

1. Field activities:
 - o Borings
 - o Trenches
 - o Test Pits
 - o Surficial Samples
 - o Cone Penetrometer Tests
2. Office activities:
 - o Laboratory Tests
 - o Data Analyses and Interpretations

The procedures used in the various activities are described in the following sections.

A5.1 BORINGS

A5.1.1 Drilling Techniques

The borings were drilled at designated locations using rotary techniques.

The drilling rig was a truck-mounted Failing 1500 with hydraulic pulldown. The borings were nominally 4-7/8 inches (124 mm) in diameter and 100 feet (30 m) deep. A bentonite-water slurry was used to return soil cuttings to the surface. A tricone drill bit was used for coarse-grained soils and a drag bit for drilling in fine-grained soils.

A5.1.2 Method of Sampling

A5.1.2.1 Sampling Intervals

Soil samples were obtained at the following nominal depths as well as at depths of change in soil type:

- 0' to 10' (0.0 to 3.0 m) - Pitcher or drive - samples at 3' intervals
- 10' to 30' (3.0 to 9.1 m) - Pitcher or drive - samples at 5' intervals
- 30' to 100' (9.1 to 30.5 m) - Pitcher or drive - samples at 10' intervals

A5.1.2.2 Sampling Techniques

a. Ertec Drive Samples: Ertec drive samplers were used to obtain relatively undisturbed soil samples. The Fugro drive sampler is a ring-lined barrel sampler with an outside diameter of 3.0 inches (76.2 mm) and inside diameter of 2.50 inches (63.5 mm). It contains 12 individual 1-inch- (25.4-mm) long

rings and is attached to a 12-inch- (30-cm) long waste barrel. The sampler was advanced using a downhole hammer weighing 300 pounds (136 kg) with a drop of 24 inches (61.0 cm).

The number of blows required to advance the sampler for a 6-inch (15-cm) interval were recorded. Samples obtained were retained in the rings, placed in plastic bags with manually twisted top ends, and sealed in plastic sample containers. Each sample was identified with a label indicating job number, boring number, sample number, depth range, Unified Soil Classification Symbol (USCS), and date. Ring samples were placed in foam-lined steel boxes.

b. Pitcher Samples: The Pitcher sampler was used to obtain undisturbed soil samples. The primary components of this sampler are an outer rotating core barrel with a bit and an inner stationary, spring-loaded, thin-wall sampling tube which leads or trails the outer barrel drilling bit, depending on the hardness of the material penetrated. The average inside diameter of the sampling tubes used was 2.87 inches (73 mm). Before placing the Pitcher tube in the outer barrel, the tube was inspected for sharpness and protrusions.

The Pitcher sampler was then lowered to the bottom of the boring, and the thin-walled sampling tube advanced into the soil ahead of the rotating cutting bit by the weight of the drill rods and hydraulic pulldown. The thin-walled sampling tube was retracted into the core barrel and the sampler was brought to the surface. After removal of the sampling tube from the core barrel, the length of the recovered soil sample was measured and recorded. Before preparing and sealing the tube, the drilling fluid in the Pitcher tube was removed. Cap plugs were taped in place on the top and bottom of the Pitcher tube and sealed with wax. When Pitcher samples could not be retrieved without disturbance, they were clearly marked as "disturbed." Each sealed Pitcher tube was labeled as explained under "Ertec Drive Samples" and then placed vertically in foam-lined wooden boxes.

c. Bulk Samples: Bulk samples from rotary drilling were obtained by screening the returning drilling fluid to obtain wash samples. Recovered samples were placed in plastic bags and labeled as previously explained.

A5.1.3 Logging

All soils were classified in the field by the procedures outlined in Section A5.5, "Field Visual Soil Classification," of this Appendix. Rock encountered in the borings was described according to classifications given in Travis (1955) and Folk (1974). The following general information was entered on the boring logs at the time of drilling: boring number; project name, number, and location; name of drilling company and driller; name of logger and date logged; and method of drilling and sampling, drill bit type and size, driving weight

and average drop as applicable. As drilling progressed, the soil samples recovered were visually classified as outlined in Section A5.5, "Field Visual Soil Classification," and the description was entered on the logs. Section A5.5 also discusses other pertinent data and observations made, which were entered on the boring logs during drilling.

A5.1.4 Sample Storage and Transportation

Samples were handled with care, drive sample containers being placed in foam-lined steel boxes, while Pitcher samples were transported in foam-lined wooden boxes. Particular care was exercised by drivers while traversing rough terrain to avoid disturbing the undisturbed samples. Whenever ambient air temperatures fell below 32°F, all samples were stored in heated rooms during the field work and transported to Ertec Western's Long Beach laboratory in heated cabins in back of pickup trucks.

A5.2 GROUND-WATER OBSERVATION WELLS

A5.2.1 Purpose

Ground-water observation wells were installed to determine:

- a. The elevation of the ground-water surface or table and its variation with the season of the year,
- b. The location of perched water tables,
- c. The location of aquifers, and
- d. The presence of artesian pressures.

A5.2.2 Drilling Equipment

See Section A5.1.2 for a complete description.

A5.2.3 Procedure

- a. Installed ground-water observation well (casing 2-inch [51-mm] PVC pipe) in wells (4 7/8-inch [124-mm] diameter) drilled at the designated locations using rotary wash techniques.
- b. The wells were drilled to the depths specified on the field maps (150 or 200 feet [45.7 or 61.0 m]) or to 30 feet (9.1 m) below the water table, if determinable at the time of drilling.
- c. REVERT drilling mud (bio-degradable) or equivalent, where practical, was used. If the REVERT mud was not adequate for returning gravelly cuttings to the surface, then a thin normal mud was used.

- d. Obtained wash samples every 10 feet (3.0 m) or at changes in the soil type. Prepared boring log, placed samples in a plastic bag, and labelled each sample.
- e. Described all samples in detail on the log for each well. Filled out the sample inventory sheets.
- f. Upon completion of the well, the prepared 2-inch (51-mm) PVC casing was inserted to the bottom of the well and the well was flushed clean of drilling mud and loose cuttings by circulating water down the casing.
- g. When flushing was complete (clear return water), the PVC casing was raised so that its bottom end was approximately 5 feet (1.5 m) above the bottom of the boring. Carefully holding the PVC casing in position; pea gravel was back-filled to approximately 30 feet (9.1 m) above the bottom of the PVC casing.
- h. About 2 feet (0.6 m) of the PVC casing was left above the ground surface. The activity locations and well number were written on PVC with a felt tip marker. Vented the well cutting a 3-inch vertical slot at the top of the PVC with hacksaw. Cap the well. Installed a 2-inch x 4-inch x 36-inch long wooden board or standard metal fence post adjacent to the well to prevent cattle from breaking the PVC. Painted the top of the post with an orange spray paint.
- i. To prevent the entrance of surface water into the well, sealed and back-filled the top 3 to 4 feet (0.9 to 1.2 m) with cuttings, empty mud sacks, small bentonite mud cakes, and local dry soil. Sloped the fill (local surface soil) at the top of the hole away from the pipe.

A5.3 TRENCHES, TEST PITS, AND SURFICIAL SAMPLES

A5.3.1 Excavation Equipment

The trenches, test pits, and surficial samples were excavated using a rubber tire-mounted Case 580C backhoe with a maximum depth capability of 14 feet (4.3 m).

A5.3.2 Method of Excavation

Unless caving occurred during the process of excavation, the trench width was nominally 2 feet (0.6 m). Trench depths were typically 14 feet (4.2 m), and lengths ranged from 10 to 16 feet (3.0 to 4.9 m). Test pits were nominally 2 feet (0.6 m) wide, 5 feet (1.5 m) deep, and ranged from 5 to 10 feet (1.5 to 3.0 m) in length. Surficial sample excavations were typically 2 feet (0.6 m) wide, 2 feet (0.6 m) deep, and about 3 to 5 feet (0.9 to

1.5 m) long. The trench and test pit walls were vertical. However, where surface materials were unstable, the trench walls were sloped back to a safe angle to prevent sloughing during the completion of excavation and logging. The excavated material was deposited on one side at least 4 feet (1.2 m) from the edge of the trenches in order to minimize stress loads at the edges. The excavations were backfilled with the excavated material and the ground surface was restored to a condition as conformable with the surrounding terrain as practicable.

A5.3.3 Sampling

The following sampling procedures were generally followed for all trenches, test pits, and surficial samples:

- o Representative bulk soil samples (large or small) were obtained in the top 2 feet (0.6 m). If the soil type changed in the top 2 feet, bulk samples of both the soil types were obtained. In addition, bulk samples of all soil types encountered at different depths in the excavation were obtained. For each soil type in the top 2 to 3 feet (0.6 to 0.9 m), two large bulk samples, weighing about 50 pounds (22.7 kg) each were taken. Bulk samples from other depths were limited to one bag. When soils from two locations were similar, only a small bag sample weighing about 2 pounds (0.9 kg) was taken from the second location.
- o All large bulk samples were placed first in plastic bags and then in cloth bags. The small bulk samples were placed in small plastic bags. All sample bags of soil were tied tightly at the top to prevent spillage and tagged with the following information: project number; trench, test pit, or surficial sample number; bulk sample number; depth range in feet; Unified Soil Classification symbol; and date. The samples were transported to the field office for storage and then to Ertec Western's Long Beach office in pickup trucks.

A5.3.4 Logging

The procedures for field visual classification of soil and rock encountered from the trenches, test pits, and surficial samples were basically the same as the procedures for logging of borings (Section A5.1.3). For excavations shallower than 4 feet (1.2 m), technicians entered the excavations and logged them. Logging of the excavations deeper than 4 feet (1.2 m) was accomplished from the surface and by observing the backhoe bucket contents. Some trench walls were photographed prior to backfilling.

Each field trench, test pit, and surficial sample log included trench, test pit, or surficial sample number; project name, number and location; name of excavator; type of excavation equipment; name of logger; and date logged. As excavations proceeded, the soil types encountered were visually classified and described as outlined in Section A5.5, "Field Visual Soil Classification." Section A5.5 also discusses other pertinent data and observations made which were entered on the logs during excavation.

A5.4 CONE PENETROMETER TESTS

A5.4.1 Equipment

The equipment consisted of a truck-mounted (17.5 tons [15,877 kg] gross weight) electronic cone penetrometer equipped with a 15-ton (13,608 kg) friction cone (cone end resistance capacity of 15 tons [13,608 kg] and 4-1/2-ton [4082 kg] limit on the friction sleeve). All operating controls, recorder, cables, and ancillary equipment were housed in the specially designed vehicle which was completely self-contained. The penetrometer, the key element of the system, contained the necessary load cells and cable connections. One end of the unit was threaded to receive the first sounding rod. When carrying out the tests, hollow rods with an outside diameter of 1.42 inches (3.6 cm) and a length of 3.3 feet (1.0 m) were used to push down the cone.

The hydraulic thrust system was mounted over the center of gravity of the truck, permitting use of the full 17.5-ton truck weight as load reaction.

The cone had an apex angle of 60° and a base area of 2.3 in^2 (15 cm^2). The resistance to penetration was measured by a built-in load cell in the tip and was relayed to the surface recorder via cables in the sounding rods. The friction sleeve, having an area of 31.8 in^2 (205 cm^2), was fitted above the cone base. The local friction was measured by load cells mounted in the friction sleeve and recorded in the same manner as the end resistance. The end resistance and friction resistance were recorded on a strip chart.

A5.4.2 Test Method

Tests were performed in accordance with ASTM D 3441-75T, "Tentative Method for Deep, Quasi-Static, Cone and Friction-Cone Penetration Tests of Soil." Basically, the test was conducted by positioning the electronic cone penetrometer truck over the designated area for testing, setting the outriggers on the ground surface, checking the level of the rig, then pushing the cone into the ground at a rate of 0.79 in/sec (2 cm/sec) until refusal (defined as the capacity of the cone, friction sleeve, or hydraulics system) or the desired depth of penetration was reached.

A5.5 FIELD VISUAL SOIL CLASSIFICATION

A5.5.1 General

All field logging of soils was performed in accordance with the procedures outlined in this section. Soil samples were visually classified in the field in general accordance with the procedures of ASTM D 2488-69, Description of Soils (Visual-Manual Procedure). The ASTM procedure is based on the Unified Soil Classification System (see Table A5-1). It describes several visual and/or manual methods which can be used in the field to estimate the USCS soil group for each sample. The following section details several of the guidelines used in the field for describing soils, drilling and excavating conditions, and unusual conditions encountered.

A5.5.2 Soil Description

Soil descriptions entered on the logs of borings, trenches, test pits, and surficial samples generally included those listed as follows.

Coarse-Grained Soils

USCS Name and Symbol
Color

Coarse-Grained Soils

Range in Particle Size
Gradation (well, poorly)
Density
Moisture Content
Particle Shape
Reaction to HCl

Fine-Grained Soils

USCS Name and Symbol
Color

Fine-Grained Soils

Consistency
Moisture Content
Plasticity
Reaction to HCl

Some additional descriptions or information recorded for both coarse- and fine-grained soils included: degree of cementation, secondary material, cobbles and boulders, and depth of change in soil type.

Definitions of some of the terms and criteria used to describe soils and conditions encountered during the investigations follow.

a. USCS Name and Symbol: Derived from Table A5-1, the Unified Soil Classification System. The soils were first designated as coarse- or fine-grained.

Coarse-grained soils are those in which more than half (by weight) of the particles are visible to the naked eye. In making this estimate, particles coarser than 3 inches (76 mm) in diameter were excluded. Fine-grained soils are those in which

The graph plots Plasticity index (Y-axis, 0 to 60) against Liquid limit (X-axis, 0 to 100). A diagonal line from (0,0) to (100,100) is labeled 'Comparing spots at equal liquid limit'. Data points are categorized by soil type: CL (Clay), CH (Clay), ML (Silt), and MH (Silt). A shaded region in the upper right corner is labeled 'Toughness and dry strength increase with increasing plasticity index'.

for laboratory classification of fine grained soils

For example G.W.-G.C. well graded gravel-sand mixture with clay binder.

Field Identification Procedure for Fine Grained Soils or Fractions

These procedures are to be performed on the minus No. 40 sieve size particles, approximately $\frac{1}{4}$ in. For field classification purposes, screening it not intended, simply remove by hand the coarse particles that interfere with the tests.

[illegible]

Squeezing assay in identifying the character of the fines in a soil
Very fine clean sands give the quickest and most distinct reaction whereas a plastic clay has no reaction Inorganic silts, such as a typical loam flour, show a moderately quick reaction.

whereas a typical silt has the smooth feel of flour

clays which occur below the A-line. Highly organic clays have a very weak and spongy feel at the plastic limit.

more than half (by weight) of the particles are so fine that they cannot be seen by the naked eye. The distinction between coarse- and fine-grained can also be made by sieve analysis with the No. 200 sieve (.074 mm) size particle considered to be the smallest size visible to the naked eye. In some instances, the field technicians describing the soils used a number 200 sieve to estimate the amount of fine-grained particles. The coarse-grained soils are further divided into sands and gravels by estimating the percentage of the coarse fraction larger than the No. 4 sieve (about 1/4 inch or 5 mm). Each coarse-grained soil is then qualified as silty, clayey, poorly graded, or well-graded as discussed under plasticity and gradation.

Fine-grained soils were identified in the field as clays or silts with appropriate adjectives (clayey silt, silty clay, etc.) based on the results of dry strength, dilatancy, and plastic thread tests (see ASTM D 2488-69 for details of these tests).

Dual USCS symbols and adjectives were used to describe soils exhibiting characteristics of more than one USCS group.

b. Color: Color descriptions were recorded using the following terms with abbreviations in parentheses.

White (w)	Green (gn)
Yellow (y)	Blue (bl)
Orange (o)	Gray (gr)
Red (r)	Black (blk)
Brown (br)	

Color combinations as well as modifiers such as light (lt) and dark (dk) were used.

c. Range in Particle Size: For coarse-grained soils (sands and gravels), the size range of the particles visible to the naked eye was estimated as fine, medium, coarse, or a combined range (fine to medium).

d. Gradation: Well-graded indicates a coarse-grained soil which has a wide range in grain size and substantial amounts of most intermediate particle sizes. A coarse-grained soil was identified as poorly graded if it consisted predominantly of one size (uniformly graded) or had a wide range of sizes with some intermediate sizes obviously missing (gap-graded).

e. Density or Consistency: The density or consistency of the in-place soil was estimated based on the number of blows required to advance the Fugro drive or split-spoon sampler, the drilling rate (difficulty) and/or hydraulic pull-down needed to drill, visual observations of the soil in the trench or test pit walls, ease (or difficulty) of excavation of trench or test

pit, or trench or test pit wall stability. For fine-grained soils, the field guides to shear strength presented below were also used to estimate consistency.

- o Coarse-grained soils - GW, GP, GM, GC, SW, SP, SM, SC (gravels and sands)

<u>Consistency</u>	<u>N-Value (ASTM D 1586-67), Blows/Foot</u>
Very Loose	0 - 4
Loose	4 - 10
Medium Dense	10 - 30
Dense	30 - 50
Very Dense	>50

- o Fine-grained Soils - ML, MH, CL, CH (Silts and Clays)

<u>Consistency</u>	<u>Shear Strength</u> (ksf) (KN/m ²)		<u>Field Guide</u>
Very Soft	<0.25	<12.0	Sample with height equal to twice the diameter, sags under own weight
Soft	0.25-0.50	12.0-23.9	Can be squeezed between thumb and forefinger
Firm	0.50-1.00	23.0-42.9	Can be molded easily with fingers
Stiff	1.00-2.00	47.9-95.8	Can be imprinted with slight pressure from fingers
Very Stiff	2.00-4.00	95.8-191.5	Can be imprinted with considerable pressure from fingers
Hard	>4.00	>191.5	Cannot be imprinted by fingers

f. Moisture Content: The following guidelines were used in the field for describing the moisture in the soil samples:

Dry : No feel of moisture - dry like powder
 Slightly Moist: Much less than optimum moisture
 Moist : Near optimum moisture for soil - provides apparent cohesion
 Very Moist : Much greater than optimum moisture
 Wet : At or near saturation

g. Particle Shape: Coarse-grained soils

Angular : Particles have sharp edges and relatively plane sides with unpolished surfaces

Subangular: Particles are similar to angular but have somewhat rounded edges

Subrounded: Particles exhibit nearly plane sides but have well-rounded corners and edges

Rounded : Particles have smoothly curved sides and no edges

h. Reaction to HCl: As an aid for identifying cementation, some soil samples were tested in the field for their reaction to dilute hydrochloric acid. The intensity of the HCl reaction was described as none, weak, or strong.

i. Degree of Cementation: Based on the intensity of the HCl reaction and observation, the degree of cementation of a soil layer was described as weak to strong. Also, the following stages of development of caliche (cemented) profile were indicated where applicable.

Stage	Gravelly Soils	Nongravelly Soils
I	Thin, discontinuous pebble coatings	Few filaments or faint coatings
II	Continuous pebble coatings, some interpebble fillings	Few to abundant nodules, flakes, filaments
III	Many interpebble fillings	Many nodules and internodular fillings
IV	Laminar horizon overlying plugged horizon	Increasing carbonate impregnation

j. Secondary Material: Example - Sand with trace to some silt

Trace	5-12% (by dry weight)
Little	13-20% (by dry weight)
Some	>20% (by dry weight)

k. Cobbles and Boulders: A cobble is a rock fragment, usually rounded or subrounded, with an average diameter between 3 and 12 inches (76 and 305 mm). A boulder is a rock fragment, usually rounded by weathering or abrasion, with an average diameter of 12 inches (305 mm) or more. The presence of cobbles and/or boulders was identified by noting the sudden change in drilling difficulty or cuttings in borings or by visual observation in excavations. An estimate of the size, range, and percentage of cobbles and/or boulders in the strata was recorded on the logs.

l. Depth of Change in Soil Type: During drilling of borings, the depth of changes in soil type was determined by observing samples, drilling rates, changes in color or consistency of drilling fluid, and relating these to depth marks on the drilling rods. In excavations, strata thicknesses were measured with

a tape. All soil type interfaces were recorded on the logs by a horizontal line at the approximate depth mark.

In addition to the observations recorded relating to soil descriptions, remarks concerning drilling difficulty, loss of drilling fluid in the boring, water levels encountered, trench wall stability, ease of excavation, and other unusual conditions were recorded on the logs.

A5.6 LABORATORY TESTS

Laboratory tests were performed on selected representative undisturbed and bulk samples. All laboratory tests (except chemical tests) were performed in Ertec Western's Long Beach laboratory. The chemical tests were conducted by Pomeroy, Johnson, and Bailey Laboratories of Pasadena, California. All tests were performed in general accordance with the American Society for Testing and Materials (ASTM) procedures. The types of tests performed and their ASTM designations are summarized as follows.

<u>Type of Test</u>	<u>ASTM Designation</u>
Unit Weight	D 2937-71
Moisture Content	D 2216-71
Particle-Size Analysis	D 422-63
Liquid Limit	D 423-66
Plastic Limit	D 424-59
Triaxial Compression	D 2850-70
Unconfined Compression	D 2166-66
Direct Shear	D 3080-72
Consolidation	D 2435-70
Compaction	D 1557-70
California Bearing Ratio (CBR)	D 1883-73
Specific Gravity	D 854-58
Water Soluble Sodium	D 1428-64
Water Soluble Chloride	D 512-67
Water Soluble Sulfate	D 516-68
Water Soluble Calcium	D 511-72
Calcium Carbonate	D 1126-67
Test for Alkalinity (pH)	D 1067-70

A5.7 DATA ANALYSIS AND INTERPRETATION

A5.7.1 Preparation of Final Logs and Laboratory and Field Test Summary Sheets

The field logs of all borings, trenches, test pits, and surficial sample excavations were prepared by systematically combining the information given on the field logs with the laboratory test results. The resultant logs include generally the following information: description of soil types encountered; sample

types of intervals, lithology (graphic soil column); estimates of soil density or consistency; depth locations of changes in soil types; remarks concerning trench wall stability; drilling difficulty, cementation, and cobbles and boulders encountered; and the total depth of exploration. Laboratory test results presented in the logs include dry density and moisture content; percent of gravel, sand, and fines; and liquid limit and plasticity index. Also, miscellaneous information such as surface elevation, surficial geologic unit, date of activity, equipment used, and dimensions of the activity is included on the log.

Laboratory data were summarized in tables. All samples which were tested in the laboratory were listed. Results of sieve analyses, hydrometer, Atterberg limits, in-situ dry strength and moisture content tests, and calculated degree of saturation and void ratio were entered on the tables. Test summary sheets for triaxial compression, unconfined compression, direct shear, consolidation, chemical, CBR, and compaction tests were prepared separately.

The Cone Penetrometer Test results consist of continuous plots of cone resistance, friction sleeve resistance, and friction ratio versus depth from ground surface. Beside the plot is shown a soil column with USCS soil types encountered at the test location.

Volume II titled "Geotechnical Data" presents the following finalized basic engineering data.

Boring Logs	Section II - 6.0
Trench and Test Pit Logs	Section II - 7.0
Surficial Sample Logs	Section II - 8.0
Laboratory Test Results	Section II - 9.0
Cone Penetrometer Test Results	Section II - 10.0

A5.7.2 Soil Characteristics

A5.7.2.1 General

The soil characteristics are discussed in two parts, surface soils and subsurface soils. The following three tables were prepared and are presented in Sections 3.3 and 3.4 of the report.

1. Characteristics of Surficial Soils;
2. Thickness of Low-Strength Surficial Soils; and
3. Characteristics of Subsurface Soils.

The following sections, A5.7.2.2 and A5.7.2.3, explain the data analyses and interpretation used in preparing the above tables.

A5.7.2.2 Surface Soils

In order to define the characteristics of the surficial soils, data from trenches, test pits, borings, surficial soil samples,

cone penetrometer tests, and surficial geologic maps were reviewed in conjunction with the laboratory test results. The soils were then grouped into three categories of soils with similar general characteristics. These categories, their descriptions, and associated characteristics were tabulated. This table (Characteristics of Surficial Soils, Table 3-1) includes soil descriptions by the Unified Soil Classification System, predominant surficial geologic units, the estimated areal extent (percent) of each category, important physical properties summarized from laboratory test results, and certain road design related data.

The important physical properties summarized include the estimated cobbles content, grain-size analyses, and Atterberg limits. Ranges for these properties were determined from the field logs and laboratory test results. These ranges are useful for categorizing soils, evaluating construction techniques, and providing data for preliminary engineering evaluations and for use by other MX participants.

Road design data presented in Table 3-1 were developed from field and laboratory tests and consist of three distinct groups:

1. Laboratory test results;
2. Suitability of soils for road use; and
3. Low-strength surficial soil.

These road design related data were considered important because roads (interconnecting and secondary) constitute a major portion of the geotechnically related costs for the vertical and horizontal shelter basing mode. The following paragraphs briefly discuss the development of road design data.

a. Laboratory Test Results: These include ranges of maximum dry density, optimum moisture content (ASTM D 1557-70) and CBR (ASTM D 1883-73) at 90 percent relative compaction for each soil category. The maximum dry density and optimum moisture content are important quality control parameters during roadway construction. California Bearing Ratio is the ratio of the resistance to penetration developed by a subgrade soil to that developed by a specimen of standard crushed-rock base material and is the basis for many empirical road design methods used in this country.

b. Suitability of Soils for Road Use: Included in this group is suitability of soils for use as road subgrade, subbase, or base. Parameters used to make these qualitative assessments were characteristics related to CBR, frost susceptibility, drainage, and volume change potential. The following guidelines were used in estimating the suitability of soils for road use.

1. Suitability as a road subgrade.

Very Good - soils which can be compacted with little effort to high CBR values (CBR >30), exhibit low frost

susceptibility, fair to good drainage, and low volume change potential.

- Good - soils which can be compacted with some effort to moderate CBR values (CBR 15-30), exhibit moderate frost susceptibility, fair drainage, and medium volume change potential.
- Fair - soils which can be compacted with considerable effort to moderate CBR values (CBR 15-30), exhibit moderate to high frost susceptibility, fair to poor drainage, and medium volume change potential.
- Poor - soils which require considerable effort for compaction to even low CBR values (CBR <15), exhibit high frost susceptibility, poor drainage, or high volume change potential. These soils should generally be removed and replaced with better quality material.

2. Suitability as road subbase or base.

- Good - soils which exhibit negligible frost susceptibility, good drainage, and negligible volume change potential.
- Fair - soils which require some treatment or processing to upgrade for use.
- Poor - soils which would require relatively extensive processing or soil stabilization to upgrade for use.
- Not Suitable - soils which cannot be modified to give adequate roadway support.

The parameters used in the aforementioned suitability ratings are discussed in the following paragraphs.

- i. CBR Characteristics: California Bearing Ratio, which is commonly used for road design, is dependent on soil type. During Verification studies, a limited number of CBR tests were performed on several soil types which were representative of the surficial soils in the various Verification sites. Based on these test results, a relationship between CBR and percent fines (percent passing through No. 200 sieve) was established and is shown in Figure A5-1. Envelopes for clays and granular soils with plastic fines and silts and granular soils with nonplastic fines are shown in the figure. This plot was used to estimate the range of laboratory CBR values for the various surficial soil categories.

EXPLANATION

- △ Gravels with nonplastic fines (GM, GW, GP, GP-GM, GW-GM)
- ▲ Gravels with plastic fines (GC, GC-GM)
- Sands with nonplastic fines (SP, SW, SM, SP-SM, SW-SM)
- Sands with plastic fines (SC, SC-SM)
- Silts (ML)
- Clays (CL, CH, CL-ML)
- Envelope for silts and granular soils with nonplastic fines
- Envelope for clays and granular soils with plastic fines

NOTES:

1. Fines correspond to soil passing through No 200 (0.074mm opening) sieve.
2. California Bearing Ratio at 90% relative compaction.
3. Soil types (GM, SC) are based on Unified Soil Classification System.

12

ii. Other Characteristics: These characteristics pertain to frost susceptibility, drainage, and volume change potential. They were estimated based on the physical properties of the soils, results of consolidation tests (for volume change potential), published literature, and our experience. Following are the definitions of these characteristics.

1. Frost susceptibility is defined as potential for detrimental ice segregation upon freezing or loss of strength upon thawing.

Low	- negligible to little potential
Moderate	- some potential
High	- considerable potential

2. Drainage characteristics pertain to internal movement of water through soil.

Good	- materials which drain rapidly and do not tend to plug with fines
------	--

Fair	- natural internal drainage is fairly rapid but there is some tendency for plugging of voids with fines
------	---

Poor	- internal drainage is somewhat slow and plugging with fines can often occur
------	--

Practically Impervious	- materials which exhibit almost no natural internal drainage
------------------------	---

3. Volume change potential corresponds to soil swelling or shrinkage due to change in moisture content.

Low	- 0 to 2 percent volume change
Medium	- 2 to 4 percent volume change
High	- > 4 percent volume change

c. Low-Strength Surficial Soil: The roads for the MX system will be built on existing ground surface with minimum cut and fill. Therefore, the costs of roads depend on the consistency (or strength) of the surficial soil. In order to evaluate the strength of the surficial soils, cone penetrometer test results were used.

Low-strength surficial soil is defined as soil which will perform poorly (failure of subgrade) as a road subgrade at its present consistency when used directly beneath a road section. In order to define "low strength" using CPT results, the following four approaches were pursued. These approaches are subjective and qualitative and are based on our experience as well as published literature.

- i. Field visual observations: During logging of the borings, the excavation of trenches, test pits, and obtaining surficial soil samples, consistency or compactness of the surficial soils was described qualitatively. A detailed comparison of the CPT results (cone end resistance) and the consistency of the soils was done for different soil types. Using engineering judgment, an upper limit cone resistance was established which encompassed a majority of the soils likely to perform poorly as road subgrades.
- ii. Standard Penetration Test (SPT): SPT is very widely used and accepted in geotechnical engineering practice in this country. A study of available literature revealed that the ratio of cone resistance (q_c , tsf) to standard penetration resistance (N, blows per foot) has a certain range for different soil types. In Verification studies, limited field SPTs were performed in some valleys. Ratios of q_c/N were computed for these tests and were found to be comparable to those reported in literature for similar soil types. Using the relationships applicable to the soils present in the Verification sites, an upper limit of cone resistance, equivalent to midrange of "medium dense" category, (SPT = 10 to 30 blows per foot) was established for defining the "low-strength" surficial soils.
- iii. In-Situ Dry Density: A comparison was made between in-situ dry densities determined from Fugro Drive and Pitcher samples obtained from soil borings and CPT results at the same locations and depths. From this comparison, it was observed that identifiable trends do exist between cone resistance values and soil densities. In this case, an upper limit of cone resistance, equivalent to midrange of "medium dense" category (relative compaction), was established for defining the "low-strength" surficial soils.
- iv. Field CBR Tests: During Verification studies, field CBR tests were performed in Reveille, Railroad, Pine, Wah Wah, Steptoe, Lake, Spring, Stone Cabin, Hot Creek, and Big Smoky valleys. The procedures for conducting the CBR tests were as described in the U.S. Army Corps of Engineers' Technical Manual (TM) 5-30, pp. 2-86 to 2-96. The test results were compared to Cone Penetrometer Tests performed at the same location. A plot of average field CBR and average cone resistance was prepared and is presented in Figure A5-2. The plot shows the results of the tests in sands only, since tests in gravel and fine-grained soils were very few. Although there is considerable scatter, majority of the data points fall in a band which is shown in Figure A5-2. From this plot, a range of CPT resistance corresponding to low field CBR values (indicating low-strength surficial soils) was established.

NOTES: 1. Data are for coarse-grained soils tested in Big Smoky, Reville, Railroad, Pine, Wah Wah, Spring, Lake, Stone Cabin, Reville and Hot Creek Verification Sites.

2. Band between the upper and lower limits includes 74% of all the data points, and includes 85% non-caliche data points

3. Solid points indicates caliche data points.

4. Depth of CBR is from zero to four feet.

FIGURE A5-2

12

As a result of the preceding four approaches, the following criteria for defining low-strength surficial soil were established:

$q_c < 120$ tsf (117 kg/cm²) for coarse-grained soils
 $q_c < 80$ tsf (78 kg/cm²) for fine-grained soils

These criteria are preliminary at this stage and may be revised as more data become available from future Verification studies. The criteria were used to determine the extent of low-strength surficial soil at each CPT location. The results are tabulated in Table 3-2, "Thickness of Low-Strength Surficial Soil."

A5.7.2.3 Subsurface Soils

Characteristics of the subsurface soils were developed using data from seismic refraction surveys, borings, trenches, test pits, and laboratory tests.

The soils were divided into coarse-grained and fine-grained soils in two ranges of depth, 0 to 20 feet and 20 to 160 feet (0 to 6 m and 6 to 49 m). Physical and engineering properties of the soils were then tabulated as "Characteristics of Subsurface Soils" (Table 3-4) based on laboratory test results on representative samples. The table includes soil descriptions, Unified Soil Classification System symbols, the estimated subsurface extent of each soil group, comments on the degree of cementation, estimated cobbles content, and ranges of values from the following laboratory tests: dry density, moisture content, grain-size distribution, liquid limit, plasticity index, unconfined compression, triaxial compression, and direct shear.

The excavatability and stability of excavation walls of a horizontal or a vertical shelter were evaluated from the subsurface data using seismic velocities, soil types, shear strength, presence of cobbles and boulders, and cementation. Problems encountered during trench and test pit excavations and drilling of borings were also considered in the evaluation.
